It is stated that, in all cases, potatoes are less sensitive to poisons than are apples, differences in resistance varying from 1,000 times with anesthetics to 8 or 10 times with alkali and copper sulphate. Mercuric chlorid and copper sulphate are about equally poisonous to potatoes. Sulphuric acid, while slightly less poisonous than lead nitrate, is about 50 times as poisonous as alkali. Potatoes, like apples, are much more sensitive to poisons at high than at low temperature.

Tannic acid precipitates starch from its aqueous solution. The occasional starch grains found in apples which are resistant to hydrochloric acid are thought possibly to have been in contact with the tannic acid of the cell sap. The presence of from 0.0003 to 0.003 per cent of tannic acid distinctly retards, 0.003 to 0.06 per cent strongly retards, and 0.33 to 1 per cent practically inhibits diastatic action, this effect showing at 35° C., and being more pronounced below 20°. The cell sap of apples may contain as much as 0.1 per cent tannic acid, and bitter pit tissue appears to contain more than does normal pulp. This will protect any starch grains extruded into the cell sap from solution, and in cells bruised during the starch stage, will aid in preventing the starch from dissolving. In the bitter pit cells, however, the starch grains are in the protoplasm, and as long as this is living the tannic acid of the cell sap is not in contact with them or with diastase. Diastase solution loses its solvent action after prolonged contact with pulp of pounded apples.

It is considered as very desirable that a complete numerical analysis of the mineral constituents of bitter pit tissue in bulk be made, paying special attention to metallic elements in small amount, for the purpose of definite guidance for further investigation.

Bitter pit and sensitivity of apples to poisons, H. G. BREIDAHL and A. C. H. ROTHERA (*Proc. Roy. Soc. Victoria, n. ser.,* 27 (1914), No. 2, pp. 191-197).—Replying to the claims of Ewart above noted, referring to investigations showing an accelerating action of malt diastase, the authors hold that his tannic acid complications are not applicable to the experiments which he discusses, that his assignment of the tannic acid retardation to an action upon the starch is incorrect, and that his experimental results were obtained under conditions and with proportions of reagents entirely different from those in experiments which he criticizes.

On bitter pit and sensitivity of apples to poison, IV, A. J. EWART (*Proc. Roy. Soc. Victoria, n. ser., 27 (1914), No. 2, pp. 342–349*).—Replying to the observations of Rothera and Breidahl above noted, and also to criticisms at the September meeting of the Royal Society of Victoria, the author states that an accelerating action may be obtained if a resistant and very active diastase be used in large amount, if the tests are made at high temperatures, and if dry bitter pit pulp in which the tannic acid has been oxidized is compared with fresh pulp rich in tannic acid. Results of his own more recent tests are given and claimed to coincide closely with those which he has previously published.

The control of peach leaf curl, A. S. Horne (Jour. Roy. Hort. Soc., 41 (1915), No. 1, pp. 110-114, fig. 1).—This is an account of tests made at the

Wisley laboratory on control methods for peach leaf curl due to Exoascus deformans.

Of the two principal preparations of copper sulphate in common use, from either of which, if properly made and applied, a film of insoluble and hence nonpoisonous copper is deposited over the surface of the leaves, the metal being rendered soluble in sufficient quantity to kill the fungi when their secretions come in contact with this deposit, Burgundy mixture was chosen for the tests on account of such advantages as the procurability and easy preservation of its ingredients, the convenience in its preparation, and its freedom from gritty particles, which, in case of Bordeaux mixture, tend to clog and wear The gelatinous suspension of copper carbonate which appears when the copper and the sodium salt are mixed cold and which, while harmless to the plant, is deadly to the fungus, also increases the degree of adhesiveness, and this is further augmented by addition of a little milk. experiments thus point to the possibility of a still further increased efficiency in the use of Burgundy mixture. In most cases, excellent results followed the use of the Wisley Burgundy mixture, in which 0.75 pint milk was added to 9.75 oz. copper sulphate and 11 oz. sodium carbonate contained in 3 gal. water.

Pathological histology of strawberries affected by species of Botrytis and Rhizopus, N. E. Stevens (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 10, pp. 361–366, pls. 2).—In a previous publication (E. S. R., 31, p. 645) F. L. Stevens, reporting on some diseases of strawberries, stated that, while a species of Botrytis is the primary cause of the condition known as leaks, it merely initiates the trouble, opening the way for other saprophytes, such as Rhizopus. In order to determine as far as possible the relations of these fungi in rotting berries, the author carried on experiments, noting particularly the differences which exist in their method of attacking the fruit.

The Botrytis was found to penetrate all parts of the berry, growing within the cells as well as between them, and to ramify through the tissues of the berry, filling them with a network of mycelium. On the other hand, the mycelium of Rhizopus was found chiefly in the outer portion of the berry, the hyphæ growing between the cells, separating them, and apparently extracting the cell sap. In comparatively few cases were both fungi found on the same berry, and in no instance has the author found Rhizopus following in a berry originally infected with Botrytis. He considers that *Rhizopus* sp. is not dependent on the presence of any other fungus in its attacks on strawberries during shipment and on the market.

Notes on diseases of cultivated crops observed in 1913-14, S. F. Ashby (Bul. Dept. Agr. Jamaica, n. ser., 2 (1915), No. 8, pp. 299-327, pls. 2).—The author gives the results of observations on diseases affecting coconut palms, cacao, banana, and citrus fruits, with recommendations regarding fungicides, insecticides, and spraying outfits.

A rot of bananas, J. F. Dastur (Agr. Jour. India, 10 (1915), No. 3, pp. 278–284, pls. 3).—Reporting observations made on a disease of banana at Pusa since May, 1914, the author points out some resemblances and differences between the organism found in connection therewith, a Fusarium with a Cephalosporium stage, and that reported by Drost and Ashby (E. S. R., 29, p. 350) to be the cause of the Panama disease of bananas.

A fungus disease of banana, D. Thomatis (Bol. Dir. Gen. Agr. [Mexico], 5 (1915), No. 1, pp. 59-61).—In parts of Oaxaca and Tabasco, banana culture is threatened with serious loss from a disease which is but little known at this time, but which has been provisionally described as being associated with a fungus and as affecting the character and circulation of the sap. It may be identical with a disease of banana in the western portion of Cuba.

A disease of Mirabilis jalapa inherited according to Mendel's law, C. Correns (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. 585-616, pl. 1, figs. 11).—Attention is called to a phenomenon consisting of a mottling, slight pitting, and partial rolling of the leaves in M. jalapa. This is stated to be due to a sort of degeneration of certain palisade and overlying epidermal cells with enlargement of cells in neighboring areas, the lower leaf surface remaining relatively unchanged. The phenomenon appears to be inherited according to the Mendelian formula and may possibly throw some light on the nature and mode of inheritance of characters.

Bark scraping and bark affections, A. Sharples (Agr. Bul. Fed. Malay States, 3 (1915), No. 11, pp. 420-425).—It is stated that, while the canker of rubber trees caused by Phytophthora faberi is unknown in Malaya, what is supposedly the first bark affection known in this region has recently appeared in the form of a slow rotting of the bark, over which numerous saprophytic fungi were growing. The bark became waterlogged and subject to attack by borers, necessitating the removal of the tree.

It appeared probable that the fundamental cause of the trouble was a method of scraping supposed to stimulate the tree to an increased flow of latex. Tests made under controlled conditions are said to have shown that the removal of the outer corky layers increased the susceptibility of the tree to attack by fungi and insects. This increase of susceptibility was less if the green cork cambium was left intact, so that this is apparently the protective layer that is the most important in this connection, and not the lactiferous layer, as formerly supposed. Further discussion is given of the conditions and phases of attack by insects and fungi, and the interrelations of the two classes of parasitism.

It is considered that bark scraping of any description should be carried out with discretion, also that until more positive knowledge is obtained as to the function of the latex in the economy of the tree, a conservative attitude is desirable in connection with methods for artificially increasing the flow of latex. It is considered as a still unsettled problem of prime importance to the future of the rubber industry whether latex is a primary product, the withdrawal of which means increased activity for its replacement, or a secondary or waste product.

Bordeau mixture as a spray for rubber trees, A. SHARPLES (Agr. Bul. Fed. Malay States, 3 (1915), No. 12, pp. 447, 448).—During experiments carried out in 1914 as already noted (E. S. R., 33, p. 151) the effects of Bordeaux mixture on the rubber obtained during its use were noted, and these are briefly described in this article. It is asserted that there is little danger in using Bordeaux mixture as a spray against the attacks of fungi on rubber trees, but that trees in bearing should be rested for two or three days after such application.

[On the occurrence of Coniophora cerebella in the woods], V. MARTENS (Mat. Mikol. i Fitopatol. Ross., 1 (1915), No. 3, pp. 52-56, figs. 7).—The author observed a peculiar rot of fir trees in northern Russia, in the regions of Vologoda and Archangel. From the diseased areas adjacent to the healthy tissue, he isolated a fungus which in certain morphological characters resembles very closely C. cerebella. If further studies confirm this tentative conclusion, this, it is said, will be the first report on the occurrence of this fungus on living trees in the woods.

Mistletoe injury to conifers in the Northwest, J. R. Weir (U. S. Dept. Agr. Bul. 360 (1916), pp. 39, pls. 4, figs. 27).—According to the author, Larix occidentalis, Pinus ponderosa, P. contorta, and Pseudotsuga taxifolia are subject to attacks of Razoumofskya larieis, R. campylopoda, R. americana, and R.

douglasii in the order named. The mistletoe causes a gradual reduction of the leaf surface of the host plant, trees of all age classes being liable to infection. Excessive mistletoe infection of the lower parts, it is said, may cause the upper portion to die, resulting in the condition commonly called staghead. Seedlings from three to six years old are often killed within a comparatively short time after infection. Where the mistletoe occurs on branches, it usually causes the formation of large witches' brooms which seriously interfere with the life functions of the tree. The author claims that mistletoe can be controlled by cutting out and burning the infected trees, particular attention being paid to centers of infection.

Self-protection by some plants against Cuscuta, O. Gertz (Jahrb. Wiss. Bot. [Pringsheim], 56 (1915), Pfeffer-Festschr., pp. 123-154).—This deals with the relations of Cuscuta to various hosts as regards protective devices against its parasitic activity, more particularly acids, oils, etc., within the plant itself.

A bibliography is appended.

Free-living nematodes of Switzerland, B. Hofmänner and R. Menzel (Rev. Suisse Zool., 23 (1915), pp. 109-243, pls. 3; abs. in Jour. Roy. Micros. Soc., No. 6 (1915), p. 580).—This account of the lacustrine and terrestrial nematodes of Switzerland includes a diagnostic key and increases the number of species to 110. Eighteen new forms are described and the genus Criconema is erected.

ECONOMIC ZOOLOGY-ENTOMOLOGY.

A preliminary report upon the economic status of the British species of woodpeckers and their relation to forestry, W. E. Collinge (Jour. Bd. Agr. [London], 22 (1915), No. 8, pp. 789-791).—This preliminary report gives the results of an examination of the stomach contents of 91 specimens of three species of woodpeckers. Fully 75 per cent of the food was found to consist of injurious insects. The author concludes that woodpeckers are distinctly beneficial to forestry and merit all the protection that can be afforded them.

A new bat from Porto Rico, H. H. T. Jackson (Proc. Biol. Soc. Wash., 29 (1916), pp. 37, 38).

[A list of parasites of animals in Guam], B. H. RANSOM (Jour. Parasitology, 2 (1915), No. 2, pp. 93, 94).—A list is given of identifications made of 19 species of parasites, including 3 trematodes, 1 cestode, 9 nematodes, 5 arthropods, and 1 protozoan, collected by L. B. Barber of the Guam Experiment Station.

Agricultural entomology (Entomologia Agraria. Florence: R. Min. Agr. Indus. e Com., 1915, pp. 484, figs. 415; abs. in Rev. Appl. Ent., 4 (1916), Ser. A, No. 2, pp. 53, 54).—A manual of insects injurious to cultivated plants, field and garden crops and their products, and methods of controlling them.

[Economic entomology] (Ztschr. Angew. Ent., 2 (1915), No. 2, pp. V+265-471, figs. 63).—The papers presented in this number include the following: A Contribution to the Biology of the Body Louse (Pediculus vestimenti), by A. Hase (pp. 265-359); The Wheat Bulb Fly (Hylemyia coarctata), A Contribution to the Knowledge of Its Biology and Its Economic Importance, by R. Kleine (pp. 360-389); List of Parasitic Hymenoptera Reared at the Imperial Plant Protection Station, Vienna, by F. Ruschka and L. Fulmek (pp. 390-412); Calosoma sycophanta, Its Life History and Distribution, etc., together with Notes on C. inquisitor, by G. Holste (pp. 413-421), the former being a review of work by the Bureau of Entomology of the U. S. Department of Agriculture; New and Little-Known Plant Pests from Our Colonies, by F. Zacher (pp. 422-426); etc.

Annual report of the state entomologist for 1914, E. L. WORSHAM (Ga. Bd. Ent. Bul. 42 (1915), pp. 5-32, pls. 8).—This report presents notes upon the work of the year, including inspection and research work, seed selection and the boll weevil, experiments for the control of fruit insects and diseases, pecan insects and diseases, and truck crop pests.

Seventh annual report of the state entomologist of Indiana, C. H. Baldwin (Ann. Rpt. State Ent. Ind., 7 (1913-14), pp. 250, figs. 164).—This report (E. S. A., 31, p. 452) contains papers on the Insects of the Year 1913-14 (pp. 13-58); Diseases of the Year (pp. 59-67); Pruning and the Care of Trees in Relation to Disease and Insect Control, by A. P. Swallow (pp. 71-101); Report of the State Inspector of Apiaries, 1914 (pp. 102-104); A Program for the Treatment of Orchard Insect Pests and Plant Diseases, by C. H. Baldwin and H. F. Dietz (pp. 109-204); and a Circular of Information for Beekeepers, by B. F. Kindig (pp. 205-250).

Eighth annual report of the state entomologist of Indiana, C. H. Baldwin (Ann. Rpt. State Ent. Ind., 8 (1914-15), pp. 321, figs. 181).—This report first presents a list of Indiana nurserymen and brief accounts of the insects of the year 1914-15 (pp. 12-29), and of plant diseases during the period under report (pp. 30-41), a report of the state inspector of apiaries (pp. 42-48), and the text of the horticultural and bee inspection laws of Indiana, together with a résumé of the nursery inspection laws of the other States and Canada (pp. 49-85). It also includes a revision of A Program for the Treatment of Orchard Insect Pests and Plant Diseases (pp. 89-190), noted in the preceding abstract, and a paper on The Coccidæ or Scale Insects of Indiana, by H. F. Dietz and H. Morrison, with drawings by R. E. Snodgrass (pp. 195-321). Sixty-two valid species of scales recognized as occurring in Indiana are described and keys given for their separation. A field key to the scales based upon superficial characters is included.

Minnesota state entomologist's reports index, O. J. Wenzel (Minn. State Ent. Circ. 38 (1916), pp. 40).—This is an index to the 15 annual and biennial reports of the state entomologist of Minnesota, published between 1895 and 1914, together with an appendix listing other publications of the state entomologist and the division of entomology of the University of Minnesota.

[Insect pests in New Hampshire], W. C. O'KANE (N. H. Dept. Agr., State Moth Work Circs. [1912], Nos. 1, pp. 4, figs. 4; 2, pp. 4, figs. 4; 3, pp. 4; 4, pp. 2; 1915, No. 5, rev., pp. 4).—These several circulars deal with the gipsy moth, the brown-tail moth, the control of the gipsy moth in woodlands and orchards, public measures against the gipsy and the brown-tail moths, and the control of the gipsy moth, the last named being previously noted (E. S. R., 32, p. 850).

Tenth report of the state entomologist and plant pathologist of Virginia, 1914-15, W. J. Schoene (*Rpt. State Ent. and Plant Path. Va.*, 10 (1914-15), pp. 75, pls. 3, figs. 5).—This biennial report (E. S. R., 31, p. 248) first presents an outline of work for the two-year period from October 1, 1913, to September 30, 1915, followed by a Report of Inspection Work, 1914-15, by W. J. Price (pp. 9-15), and an account and the text of the Court Decision Upholding the Cedar Rust Law, by the author (pp. 16-29).

A Report on the Investigation of Insects Affecting Truck Crops in Virginia, by L. B. Smith (pp. 30-63), next presented, deals in large part with investigations of the biology of the green pea aphis (*Macrosiphum pisi*) in eastern Virginia. An account of work with control measures for this insect has been previously noted (E. S. R., 32, p. 652). This aphid has for the past 15 years been causing serious losses to the pea growers in eastern Virginia. The damage to the spring crop occurs usually during May and June, while the fall crop is subject to attack during September and October. Severe attacks of the aphis

cause the plants to wither, become dry, and finally die, usually before the crop has matured. This aphid changes food plants usually four times during the season, those serving as hosts in this region including crimson clover, garden peas, red clover, sweet peas, Lespedeza sp., vetches, alfalfa, sweet clover, alsike, white clovers, and shepherd's purse.

"In general the pea aphid passes the winter on clovers, in April they migrate to garden peas, upon which they feed until the first part of July. They then go to the summer food plants, which include sweet clover, Lespedeza sp., alfalfa, and the clovers. During August they return to garden peas, where they remain until November and December, when they migrate for the fourth time, this time returning to the clovers, upon which the winter is passed. The foregoing statements of the migrations apply to the majority of the aphids, for doubtless many individuals continue to breed on the clovers throughout the year.

"No true oviparous females or the eggs of the species, have been found in this region, although a few males were collected on garden peas in November, 1914. The viviparous females which pass the winter enter into hibernation during December and commence reproducing in March. No reproduction, and very little feeding, has been observed during January and February.

"The presence of many parasitic and predacious enemies, together with the aphidid fungus, tend to keep the aphids in check during the summer.

"In 1914 there were 21 generations produced between May 1 and December 10. In 1915 there were 22 generations between March 19 and December 5. The age at which females began reproduction varied from 7 to 26 days, it being noticeably longer in the spring and fall than during the summer. From a series of 87 individuals the average age at which reproduction commenced was 12.1 days. The length of the reproductive period varied from 4 to 36 days, an average for the two seasons of 84 records being 18.1 days. The period between the birth of the last young and the death of the female, from 74 records, averaged 1.2 days. The average length of life of viviparous females, from 83 records, including two seasons, was 31.7 days. The average length of life of hibernating females was 134 days.

"The number of young born per day by viviparous females varied from 1 to 11. The total maximum number born by any one female was 142. The average number born per female, from 83 records, was 80.7 young. The fecundity of the females was greatest during July, August, and the early part of September. It has been found that the wingless viviparous females apparently mature in less time and have greater reproductive power than do the winged forms. The fecundity of the winged hibernating females is not as great as that of the wingless or the winged viviparous summer forms.

"The pea aphis molts four times. An average of the lengths of the first four instars, from 60 individual records, is as follows: First instar, 1.6 days; second instar, 2.6 days; third instar, 2.8 days; fourth instar, 2.4 days; thus making the average age at the time of the fourth molt, 9.6 days. As might be expected, the period of development was considerably shorter during the warmer summer months than during the cooler periods in the spring and autumn."

Observations on the Life Histories and Habits of the Species of Aphids Most Common on the Cultivated Apple (Malus malus) in Virginia (Blacksburg) during the Season of 1915, including the oat aphis (Aphis avena), the rosy aphis (A. sorbi), and the apple aphis, and a list of the more recent literature relating to these species, by M. T. Smulyan, are appended (pp. 64-75). A. sorbi is apparently the most injurious of the three in Virginia and the apple aphis probably the least. The author reports that his investigations of the alternate or summer host plants of A. sorbi in Virginia have substantiated the

findings of Ross in Canada that apterous and alate viviparous females and pupæ occur on the common or broad-leaved plantain (*Plantago major*) and English or narrow-leaved plantain (*P. lanceolata*).

Notes on the acarid and insect enemies of cultivated plants observed in the Province of Turin in 1913, G. Della Beffa (Ann. R. Accad. Agr. Torino, 57 (1914), pp. 35-78, figs. 12).—These notes relate to 342 insect pests.

Contribution to the knowledge of West African insect pests of plants, F. Zacher (*Tropenpflanzer*, 18 (1915), No. 9-10, pp. 504-534, figs. 35).—A general survey of the field, including a list with the scientific, German, and local names of 82 insects, the nature of their injury, and the locality where found.

Annual report of the government entomologist, W. SMALL (Ann. Rpt. Dept. Agr. Uganda, 1915, pp. 71-78).—A report upon the occurrence of and work with the insect enemies of coffee, cacao, rubber, cotton, etc.

Report of the entomologist, W. H. Patterson (Govt. Gold Coast, Rpt. Agr. Dept., 1914, pp. 21-24).—A brief report of the work of the year.

The ecology of some endophytic larvæ.—Observations and experiments, E. RABAUD (Bul. Sci. France et Belg., 46 (1912), No. 1, pp. 1-28, fig. 1; 48 (1914), No. 2, pp. 81-159, fig. 1).—The first paper deals with Olethreutes oblongana in the heads of wild teazel (Dipsacus sylvestris); the second with Myelois cribrella and some other caterpillars which live in the heads of members of the thistle tribe.

Locusts (Agr. News [Barbados], 14 (1915), No. 343, p. 202).—An invasion of Trinidad by the South American migratory locust (Schistocerca paranensis) is reported. Large swarms began to arrive on Chacachacare Island from Venezuela on May 30.

A preliminary list of the Jassoidea of Missouri with notes on species, E. H. Gibson and E. S. Cogan (Ohio Jour. Sci., 16 (1915), No. 2, pp. 71-78).

The stick-lac insect, L. Duport (Bul. Écon. Indochine, n. ser., 18 (1915), No. 112, pp. 182-189).—An account is given of the biology of this scale (Tachardia lacca) and its natural enemies.

The development of the Phylloxera vastatrix leaf gall, H. R. ROSEN (Science, n. ser., 48 (1916), No. 1102, pp. 216, 217).—The author finds that the withdrawal by phylloxera of a large amount of material at one point from tender growing leaves with subsequent changes in tension and pressure at that point and certain structural peculiarities of the gall itself all suggest the sucking action as the initial stimulus for gall production.

Woolly pear aphis, A. C. Baker and W. M. Davidson (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 10, pp. 351-360, fig. 1).—The woolly aphis known for some years to attack pear roots in California and previously considered to be the woolly apple aphis (Eriosoma lanigerum), which it resembles in both habit and structure, has been found by the authors to represent a new species which they here describe as E. pyricola. In addition to the description the authors consider its history, habits, spread, and biology. The species occurs over practically all the pear sections of northern and central California, where in some regions it is very destructive, and is recorded as having been collected at Wooster, Ohio, in the fall of 1897 on roots of pear stock received from France the preceding spring. It appears to have been present in California for more than 20 years, having ruined some 2,000 French seedlings in one block about ten years ago.

This species works entirely underground, apparently attacking the roots of all types of pears, although especially injurious to the French wild stock so largely used in California as a stock for the Bartlett. It works especially upon the smaller fibrous rootlets and may be encountered on any such rootlets within the topmost 3 ft. of soil and perhaps deeper. The infestations are usually

[Vol. 35

heavier on the rootlets near the trunk, but frequently the aphids are as abundant 10 or 12 ft. from the stem. Badly stunted growth and early falling of the foliage are characteristic of its injury on young trees. "Injury and death are due to heavy summer and autumn infestations on the fibrous rootlets and to the inability of the tree to replace the destroyed roots quickly enough to afford plant food for the vegetative portion. . . . In orchards and districts where conditions favor large productions of winged forms, or migrants, spring and early summer infestations are small, denoting that few insects passed the winter on the roots. After the month of June, however, such infestations multiply rapidly and become very large by September, the month in which the fall migrants are produced in greatest abundance. After September there remain small wingless colonies which increase but little until the summer following. The winged forms are produced in abundance on heavy dry clay soils which crack in summer and autumn. . . . Occasionally the wingless infestations are severe the year round; where this is so, in the early part of the year there is caused a considerable stunting of growth and more or less weakening, unless the trees can put out plenty of new rootlets to replace those injured and destroyed. This condition has been noted especially on light clay soils where poor cultivation was employed."

In considering the biology of this species a comparison is made of *E. pyricola* with *E. lanigerum* and of the fall migrants of *E. pyricola*, *E. lanigerum*, and *E. americanum*. The new species is easily distinguished from *E. ulmi* from the fact that segment V bears prominent transverse sensoria, and the wingless forms can be distinguished from those of *E. lanigerum* by the structure of the compound wax pores and the wingled forms by the antennæ.

Capsid bugs, J. C. F. FRYER (*Jour. Bd. Agr.* [*London*], 22 (1916), No. 10, pp. 950-958, pls. 2).—This is a brief summary of the present state of our knowledge with regard to the injury to apple trees and fruit now generally ascribed to plant bugs of the family Capsidæ.

Ocencyrtus pacificus, a new egg parasite from Fiji, J. WATERSTON (Bul. Ent. Research, 6 (1915), No. 3, pp. 307-310, figs. 1).—This parasite was reared from the eggs of the bean bug (Brachyplatys pacificus) at Rarawai, Viti Levu, Fiji.

The insect vector of uta, a Peruvian disease, C. H. T. Townsend (Jour. Parasitology, 2 (1915), No. 2, pp. 67-73, fig. 1).—A disease known as uta, which occurs on the west face of the Andes in Peru, has been proved to be due to a Leishmania. Two species of gnats of the genus Forcipomyia are said to have been proved capable of transmitting this Leishmania. "It is highly probable that the various forms of leishmaniasis thus far known are due to as many species of herpetomonads originally parasitic in the gut of the insect carriers concerned, and that, with regard to the occurrence in man, these herpetomonads are as yet in the stages of parasitism ranging from habitually abnormal or frequent to merely accidental or infrequent."

A classification of the Lepidoptera based on characters of the pupa, Edna Mosher (Bul. Ill. State Lab. Nat. Hist., 12 (1916), Art. 2, pp. 13-159, pls. 9).—Investigations by the author have led to this classification, based on pupal characters. An attempt has also been made to throw some light on the relationships existing between the different groups.

Tineid moths of Central America, Lord Walsingham (Biol. Cent. Amer., Zool., Lepidoptera-Heterocera, 4 (1909-1915), pp. XII+482, pls. 10; rev. in Nature [London], 96 (1916), No. 2411, pp. 533, 534).—The several fascicles of this volume deal with the Tineina. In the preparation of this work the author has been assisted by J. H. Durrant and A. Busck, the latter of the Bureau of Entomology of the U. S. Department of Agriculture.

The introduction and establishment in Canada of the natural enemies of the brown-tail and gipsy moths, J. D. TOTHILL (Agr. Gaz. Canada, 3 (1916), No. 2, pp. 111-116, fig. 1).—A detailed account is given of the distribution of the parasitic and predactous enemies of these moths in Canada, together with a map showing their distribution.

The brown Ctenucha (Ctenucha brunnea), E. O. Essig (Jour. Ent. and Zool., 7 (1915), No. 4, pp. 241-244, pl. 1).—This lepidopteran occurs in the coast region from San Francisco to the southern part of California, where it is found feeding on the leaves of California wild rye (Elymus condensatus). The caterpillars are effectively parasitized by a new species of Protapanteles, which in confinement was reared from about 95 per cent of the caterpillars. This parasite is attacked by a hyperparasite (Hemiteles n. sp.).

The larvæ of a noctuid moth also feeds on this host plant at Ventura and is said to be much more destructive to the plant. It burrows into the centers of the stems in which it feeds and remains until ready to pupate.

Cutworms and their control in corn and other cereal crops, W. R. Walton and J. J. Davis (U. S. Dept. Agr., Furmers' Bul. 739 (1916), pp. 3, fig. 1).—A brief popular account.

The true army worm and its control, W. R. Walton (U. S. Dept. Agr., Farmers' Bul. 731 (1916), pp. 12, figs. 8).—This popular account of (Heliophila) Cirphis unipuncta and means for its control is of general interest to crop growers.

The clover leafhopper and its control in the Central States, E. H. Gibson (U. S. Dept. Agr., Farmers' Bul. 737 (1916), pp. 8, figs. 5).—An account of Agallia sanguinolenta, its habits and mode of attack, together with information as to the control of outbreaks in alfalfa and clover fields.

The species is distributed generally throughout the United States and its range extends into southern Canada and Mexico. Its primary injury is produced by direct feeding, as many as 600 individuals having been counted on a single plant. A second form of injury is produced by the forcing of the eggs into the stem and leaf tissue by the adult female, which causes a distortion of the surrounding tissue and often results in a gall-like formation. Its principal host plants are leguminous, including alfalfa, clover, cowpeas, and vetch, but it is common on meadow and pasture lands and feeds on a number of cultivated as well as native grasses.

The eggs hatch in from 5 to 12 days in summer in the latitude of southern Illinois. Five molts are passed by the nymphs, which require from 18 to 35 days, with an average of 25 days for development. The number of generations produced varies annually with the weather and with the latitude, there usually being three distinct broods in southern Missouri and northern Arkansas. In the Northern States the clover leafhopper hibernates in the adult stage, at the base of clumps of grass and weeds and under dried leaves and trash. Nymphs can not long survive cold weather, and it is not probable that the eggs survive over winter. In the extreme Southwest the leafhopper is active throughout the entire year.

The hopperdozer, a frame for which is illustrated, is recommended for use in its direct control. Mention is also made of the importance of burning rubbish and waste vegetation, close cutting or pasturing of grasslands, and the early cutting of alfalfa as control measures.

The dipterous family Scatopsidæ, A. L. Melander (Washington Sta. Bul. 130 (1916), pp. 3-18, pls. 2).—In this account, 18 species of Scatopsidæ from the United States are recognized, six of which are described as new to science. It is pointed out that these flies are of economic importance through their habit of breeding in filth.

Notes on beet or mangold fly, A. D. IMMS (Jour. Bd. Agr. [London], 22 (1915), No. 9, pp. 881-884).—A brief account of the distribution, life history, and methods of control of Pegomya hyoscyami betw. A detailed account by Cameron of the life history of this species has been previously noted (E. S. R., 32, p. 351).

The yellow currant and gooseberry fruit fly (Epochra canadensis), L. A. WHITNEY (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 4, pp. 152-157, flgs. 5).— This fruit fly, which is generally distributed throughout the currant and gooseberry growing districts of the United States and Canada, is in California apparently confined to the central and northern parts of the State. Technical descriptions are given of its life stages, together with a summary of control work with the cherry fruit flies in New York State, adapted from New York Cornell Experiment Station Bulletin 325, previously noted (E. S. R., 29, p. 55).

Life histories and methods of rearing Hessian fly parasites, C. M. PACKARD (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 10, pp. 367-381, pls. 2).—This report of studies made of the life history, habits, and relative efficiency of Hessian fly parasites during the seasons of 1914 and 1915 deals with three hymenopterans, namely, Eupelmus allynii, Merisus destructor, and (Merisus) Micromelus subapterus. The methods of rearing found most satisfactory are first described.

The egg of *E. allynii* requires a period of from 1.5 to 5 days for incubation from July to November; from 7 to 10 days are required by the larva to pass through the five instars and complete its growth, and from 9 to 24 days for development in the pupal stage. As many as 58 eggs are recorded as having been laid by each of two females. It is stated that W. R. McConnell has ascertained that this species can reproduce parthenogenetically.

M. destructor requires from 1.5 to 4 days for its embryonic development; from 7 to 11 days for the development of the larva; and 7 to 14 days from the formation of the pupa to the emergence of the adult. A total of 39 eggs is recorded as having been laid by a single female.

M. subapterus was found to require from 1.5 to 5 days for the development of the eggs; from 7 to 10 days for the growth of the larva; and from 7 to 13 days for the development of the pupa. A total of 103 eggs is recorded as having been deposited by a single female.

The author's experiments and observations have led to the inference that only one specimen of any of the three species studied ever matures in a single Hessian fly puparium. In every instance where more than one egg or larva was placed on the same host or in the same cell, one survived and the rest were killed by that one or starved to death. This was true whether the two or more larvæ were of the same or different species.

Studies of agricultural biology.—I, Account of the glossines or tsetse flies, E. Hegh (Études de Biologie Agricole: No. 1, Notice sur les Glossines ou Tsétsés. London: Belgian Govt., 1915, pp. 148, figs. 29).—This reports studies of the tsetse flies.

A chemotropic response of the house fly (Musca domestica), C. H. RICHARDson (Science, n. ser., 43 (1916), No. 1113, pp. 613-616).—The author here presents a preliminary report on tests of the response of the house fly to a number of inorganic and organic compounds which occur as products of fermentation in barnyard manures. Negative results were obtained in all but the ammonium hydroxid and ammonium carbonate experiments.

Flytraps and their operation, F. C. BISHOPP (U. S. Dept. Agr., Farmers' Bul. 734 (1916), pp. 13, figs. 7).—A popular account of supplementary means for controlling flies.

Phyllophaga Harris (Lachnosterna Hope): A revision of the synonymy and one new name, R. D. Glasgow (Bul. Ill. State Lab. Nat. Hist., 11 (1916), Art. 5, pp. 365-379).—As stated by the author this preliminary paper is designed to indicate the progress of the work with the white grubs or May beetles and to present the changes in synonymy that a thorough study of the types has shown to be necessary.

A new species which is abundant in southern Illinois in midsummer is described as *Phyllophaga forbesi*.

On certain beetle larvæ found in sugar plantations, P. VAN DER GOOT (Arch. Suikerindus. Nederland. Indië, 23 (1915), No. 20, pp. 789-830, figs. 13; Meded. Proefstat. Java-Suikerindus., 5 (1915), No. 10, pp. 275-316, figs. 13; abs. in Rev. Appl. Ent., 4 (1916), Ser. A, No. 3, p. 89).—Descriptions are given of 16 species of beetles, the larvæ of which were collected in sugar plantations in Java during February and May, 1914, while searching for parasites of Adoretus compresesus, together with notes on their bionomics and parasites.

The cassava grubs, S. Leefmans (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 13 (1915), pp. 121, pls. 11; abs. in Rev. Appl. Ent., 4 (1916), Ser. A, No. 2, pp. 82-84).—Two beetles are said to be especially destructive to cassava in Java, namely, Leucopholis rorida and Lepidiota stigma, the former causing the greater damage. In addition to an extended account of these two pests a list is given of insects of minor importance, together with a discussion of their bionomics.

The Mexican cotton boll weevil (Ga. Bd. Ent. Bul. 39 (1914), pp. 3-24, pls. 7, flg. 1; 44 (1916), pp. 3-22, pls. 9, flgs. 7).—Popular accounts of this cotton pest are given. The first was prepared for the purpose of sounding a warning to the cotton growers of Georgia, while the second is a revised edition, giving information relating to the pest, which entered Georgia in the late summer of 1915.

The turnip gall weevil (Jour. Bd. Agr. [London], 22 (1915), No. 9, pp. 884-887, pl. 1).—This weevil (Ceuthorhynchus pleurostigma [sulcicollis]) is at times the source of considerable injury to the turnip and cabbage crops in England. It is widely distributed throughout the United Kingdom and is also well known on the Continent, being destructive in France, Russia, and Germany. Although its principal injury is to turnips and cabbage, mustard, charlock, rape, Brussels sprouts, savoy, and kohl-rabi are attacked.

The adults emerge from the pupæ in the spring and summer and oviposit on the roots of the food plants. On hatching out the young larva feeds on the roots, which causes the formation of galls. Upon completing their growth the larvæ leave the galls and pupate in the soil.

The corn and cotton wireworm in its relation to cereal and forage crops, with control measures, E. H. Gibson (U. S. Dept. Agr., Farmers' Bul. 733 (1916), pp. 7, figs. 3).—A popular account of Horistonotus uhleri, based upon studies which extended over a period of three years. A report of studies of this species in South Carolina has previously been noted (E. S. R., 33, p. 158).

On the biology of the Gramang ant (Plagiolepis longipes), P. VAN DER GOOT (Meded. Proefstat. Midden-Java, No. 19 (1915), pp. II+60; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 11, pp. 663, 664).—The author presents a detailed account of the life history and bionomics of P. longipes, which is reported to attend plant lice and coccids on the branches of coffee, etc.

Transferring bees, F. E. MILLEN (Michigan Sta. Spec. Bul. 76 (1915), pp. 16, figs. 9).—This is the first of a series of bulletins with information relating to bee management.

Fourteenth annual report of the Illinois State Beekeepers' Association, compiled by J. A. Stone (Ann. Rpt. Ill. Beekeepers' Assoc., 14 (1914), pp. 197,

figs. 21).—This report contains the proceedings of the twenty-fourth annual session of the Illinois State Beekeepers' Association, held at Springfield, November 19 and 20, 1914 (pp. 25–99), and of the seventeenth annual convention of the Chicago-Northwestern Beekeepers' Association, held at Chicago, December 17 and 18, 1914 (pp. 101–175); the by-laws as adopted by and the minutes of the National Beekeepers' Association, Denver, Colo., in February, 1915 (pp. 176–188); etc.

Bramble bees and others, J. H. Fabre, trans. by A. Teixeira de Mattos (New York: Dodd, Mead & Co., 1915, pp. VIII+456).—A popular treatise consisting of a translation of all the essays on wild bees from the author's Souvenirs Entomologiques, with the exception of those on mason bees previously noted (E. S. R., 32, p. 758). Observations of the bionomics of species of Osmia, leaf cutters (Megachile), cotton and resin bees (Anthidium spp.), and species of Halictus are given.

The hunting wasps, J. H. Fabre, trans. by A. Teixeiba de Mattos (New York: Dodd, Mead & Co., 1915, pp. VIII+427).—This popular treatise, which consists in large part of a translation of chapters on wasps from the author's Souvenirs Entomologiques, presents observations of the bionomics of species of Cerceris, Sphex, Ammophila, Bembex, etc.

A survey of the zoocecidia on species of Hicoria caused by parasites belonging to the Eriophyidæ and the Itonididæ (Cecidomyiidæ), B. W. Wells (Ohio Jour. Sci., 16 (1915), No. 2, pp. 37-59, figs. 33).—This paper presents descriptions of the types of 2 eriophyid and 30 itonidid galls on hickory leaves. In addition, forms previously described and not seen by the author have been added to give completeness to the survey of the two groups of galls.

A new oat pest (Tarsonemus spirifex), the oat mite, T. A. C. Schoevers (Tijdschr. Plantenziekten, 21 (1915), No. 4, pp. 111-130, pls. 3, figs. 2; abs. in Rev. Appl. Ent., 3 (1915), Ser. A, No. 11, pp. 664, 665).—Oats received in July from Almkerk were attacked by this mite. It has also been a source of injury to oats in some departments of France and has been found in Baden, Bavaria, and Mecklenburg. The damage done is very considerable, and at Wageningen 90 per cent of the haulms were more or less attacked.

A description of the mite and larvæ, with plates, by A. C. Oudemans forms a supplement to this paper (pp. 124-130).

The red spider on cotton and how to control it, E. A. McGregor (U. S. Dept. Agr., Farmers' Bul. 735 (1916), pp. 12, figs. 10).—A general account based upon studies previously noted (E. S. R., 32, p. 251).

FOODS—HUMAN NUTRITION.

On the digestibility of bread.—I, Salivary digestion in vitro, J. C. BLAKE (Jour. Amer. Chem. Soc., 38 (1916), No. 6, pp. 1245-1260, ftg. 1).—This paper is a report of experiments in vitro on the digestibility of bread, from which the following conclusions are drawn:

"The specificity and complexity of starches is confirmed. A number of polysaccharids are clearly recognized and differentiated, and the existence of two new ones indicated.

"The three principal ingredients of cereal starches are amylocellulose (the cell walls), amylopectin, and amylose.

"The amylose, contrary to the contention of . . . [others] passes through the stages of amylodextrin and erythrodextrin during salivary digestion, but these dextrins digest so rapidly that their presence in the digestion mixture can conveniently be demonstrated only when the enzym concentration is very low

(e. g., 1:99). Furthermore, an appreciable amount of achroödextrin enters the solution with ordinary concentrations of saliva.

"All of the dextrins under ordinary conditions disappear from the solution within 15 minutes, so that thereafter the further progress of the digestion can be followed by the polariscope, the only optically active substance then present being maltose if maltase has not been added from some outside source. As the amylose is all digested by this time, the further digestion represents action on amylocellulose and amylopectin and their products of hydrolysis.

"By slow digestion almost the entire amount of amylose present was obtained in solution as erythrodextrin at the end of 15 minutes. Hence under ordinary conditions the digestion of amylose must be almost instantaneous.

"Rose-amylose, derived from amylopectin, digests completely in four hours. This has usually been regarded as the end of starch digestion, the rose-amylose being confused with erythrodextrin.

"The amylocellulose (cell walls) digests only after more than 24 hours.

"The only differences observable in the rate of digestion of bread made from hard or soft wheat, and fermented more or less than usual, were due to the relative amounts of gluten present. When the gluten was broken down, the rate of digestion was sensibly the same.

"The cause of the greater palatability of home-baked bread was not discovered. Various pronounced effects due to fermentation by spoiled yeast were noted.

"The activity of amylases is not sensitive to small changes of temperature or of acidity produced by the organic acids found in bread; nor does their activity seem to be proportional to their concentrations. It would seem that under physiological conditions most of the amylose must be changed to dextrins in the mouth, and that these dextrins as well as most of the amylopectin and its products of hydrolysis must be digested in the stomach, whereas the digestion of the amylocellulose must take place for the most part in the intestine.

"Stale (air-dried) bread digests very slowly unless its gluten be completely broken down."

Milling and baking tests, J. A. VOELCKER (Jour. Roy. Agr. Soc. England, 76 (1915), pp. 333, 334).—As a part of the study of the influence of magnesia on wheat, conducted at the Woburn Experimental Station of the Royal Agricultural Society, milling and baking tests were made upon four samples of wheat. Two of the samples were raised on new plats of ground and two on old plats, one of each pair of samples being raised on soil to which magnesia had been added. For commercial purposes no differences were noted in the baking quality of the samples.

Nutrition investigations upon cotton-seed meal, I, Anna E. Richardson and Helen S. Green (Jour. Biol. Chem., 25 (1916), No. 2. pp. 307-318, figs. 5).—Investigating the suitability of cotton-seed meal for human consumption, the authors report in this paper a number of feeding experiments to determine the efficiency of cotton-seed meal as a food for promoting the growth, development, and reproduction of the albino rat. The results indicate that "cotton-seed meal does not contain sufficient minerals for growth, is not actively toxic, contains efficient protein, and perhaps fat-soluble growth-promoting substances, similar to those of butter fat but in less adequate quantities."

Commercial possibilities of the goosefish, H. M. SMITH (U. S. Dept. Com., Bur. Fisheries Econ. Circ. 13 (1914), pp. 5).—It is estimated that the fishermen of the Atlantic coast throw away annually about 10,000,000 of these fish, which, according to analyses of the edible portion, contain more protein than flounders

or cod and nearly as much as halibut. The goosefish is used extensively for food purposes in England, Scotland, and Germany. Recipes for the preparation of this fish are included in the circular.

Caviar: What it is and how to prepare it, L. RADCLIFFE (U. S. Dept. Com., Bur. Fisheries Econ. Circ. 20 (1916), pp. 8, figs. 3).—This pamphlet was issued especially to assist fishermen in making a better product.

Fermented milk in infant feeding, A. E. Mucklow (*Med. Rec.* [N. Y.], 89 (1916), No. 26, pp. 1134-1137).—Several formulas are given, together with directions and suggestions for their preparation.

Egg substitutes, E. Gerber (Ztschr. Untersuch. Nahr. u. Genussmtl., 31 (1916), No. 2, pp. 45-54).—Analyses are given of a number of egg substitutes. All of these preparations contained too little lecithin to be considered complete egg substitutes.

The use of wild plants as food by Indians, T. Wilson (Ottawa Nat., 30 (1916), No. 2, pp. 17-21).—A number of roots, shoots, leaves, and berries are described as having been used for food purposes by the Indians of British Columbia.

Dandelions as food, Lucile Brewer and Helen Canon (Cornell Reading Courses, 5 (1916), No. 105, pp. 79-91, pl. 1, figs. 6).—Directions are given for preparing dandelions for the table. Recipes are included.

The use of horse-chestnuts in human nutrition, H. Seeger (Chem. Ztg., 40 (1916), No. 31-32, pp. 221. 222).—The fruit of the horse-chestnut was found to contain water, 40 per cent; protein, 5 per cent; fat, 2.5 per cent; sugar, 9 per cent; starch, 42 per cent, and ash, 1.5 per cent. By extraction with water and alcohol, the bitter principle was removed, thereby yielding a good grade of flour which was satisfactorily used in bread making.

The culture, extractive content, and preservation of edible fungi, R. FALCK (Ztschr. Forst u. Jagdw., 46 (1914), No. 11, pp. 639-645, figs. 4; 47 (1915), No. 10, pp. 583-601).—Information is given regarding the culture, preparation, and preservation of edible fungi. The percentage composition of mushrooms and mushroom extracts is compared with that of meat and meat extracts.

Utilization of honey and wax, J. Tinsley (West of Scot. Agr. Col. Bul. 69 (1916), pp. 63-72).—Recipes are given.

[Food, drug, and dairy inspection] (Ann. Rpt. Bd. Health Mass., 46 (1914), pp. 401-523, fig. 1).—The work carried on under the state food and drug laws for the year ended November 30, 1914, is reviewed. The report of the analyst, H. C. Lythgoe, presents the results of the examination of 9,680 samples of foods and drugs, of which 7,385 conformed to existing standards. Reports are also included of the inspection of food products in cold storage, the inspection of slaughtered animals and meat products, and the sanitary inspection of dairies.

[Food and drug inspection], E. F. LADD and ALMA K. JOHNSON (North Dakota Sta. Spec. Bul., 4 (1916), No. 4, pp. 81-96).—Information is given regarding a number of samples of food products, toilet preparations, and patent medicines, including the text of a decision of the U. S. Supreme Court as to containers for lard.

Tenth biennial report of the dairy and food commissioner of the State of Oregon, J. D. Mickle (Bien. Rpt. Dairy and Food Comr. Oreg., 10 (1912-1914), pp. 108, figs. 22).—The work of the state dairy and food department for the two-year period ended September 30, 1914, is reviewed, and recommendations to the legislature are included. The work consisted chiefly of the inspection of dairies and other places where food was prepared or sold and the examination of samples of food products.

Preliminary report of the dairy and food commissioner for the year 1915, J. Foust (Penn. Dept. Agr. Bul. 279 (1916), pp. 53).—The work of the dairy

and food division is reviewed briefly and a summary is given showing the number of samples of food products analyzed, prosecutions terminated, etc.

Fifteenth annual report of the food and drug commissioner, G. G. Frark (Ann. Rpt. Food and Drug Comr. S. Dak., 15 (1915), pp. 200).—The work of the food and drug department for the year ended June 30, 1915, is reviewed. This included the examination of miscellaneous samples of foods, drugs, feeding stuffs, etc., and the sanitary inspection of hotels, restaurants, and rooming houses.

Biennial report of the dairy and food commissioner of Wisconsin for the period ending June 30, 1914, J. Q. EMERY (Bien. Rpt. Dairy and Food Comr. Wis., 1914, pp. 252, pls. 3, flgs. 22).—The work carried on during the period from July 1, 1912, to July 1, 1914, is reviewed at length. The report of the chemist, H. Klueter, gives the results of the examination of 1,428 samples of foods, drugs, paints, oils, etc. The report of the inspector of weights and measures is included in the publication.

In order to collect data for use in the enforcement of the net-weight law, shrinkage tests were made of flour, print butter, and cheese. Tables are given which show in detail the results of these tests.

The laws relating to the manufacture and sale of food products (Salem, Oreg.: State Printing Department, 1915, pp. 81).—This bulletin contains the texts of the laws relating to the manufacture and sale of food and dairy products, feeding stuffs, oils, and seeds. Regulations made by the dairy and food commissioner are included.

Unique nonrefrigerative methods of food, L. Lodian (Refrigerating World, 50 (1916), No. 6, pp. 25-28, figs. 3).—This article describes a number of methods for preserving food, such as air-drying, sun-desiccation, smoking, stringing, compression, etc.

What every housewife should know, W. L. WALDRON (Trenton, N. J.: [State, 1916], pp. 29, pl. 1).—This pamphlet, issued by the Department of Weights and Measures of the State of New Jersey, contains general information regarding weights and measures, and gives hints useful in the purchasing of foods.

Rise in British food prices, H. L. Washington (U. S. Dept. Com., Com. Rpts., No. 138 (1916), p. 990).—The percentage increase in the prices of a number of common foodstuffs is noted.

Retail prices, house rent, and cost-of-living indexes, G. H. Knibbs (Commonwealth Bur. Census and Statis. Aust., Labour Bul., No. 12 (1915), pp. 333-352).—A compilation of statistical data.

A study on food and the fuel value of the dietary at the New York City Municipal Sanatorium, R. J. WILSON and W. L. RATHBUN (Jour. Amer. Med. Assoc., 66 (1916), No. 23, pp. 1760-1765).—In this article descriptions are given of the methods employed in securing an adequate and economical diet for the patients and in reducing the amount of plate, table, kitchen, and ice-box waste.

A week's menu for an average Filipino family, Josefa Herrera (*Philippine Craftsman*, 4 (1916), No. 8, pp. 514-517).—Cost data are included.

The dietary of the field laborer in Spain (Bol. Agr. Téc. y Econ., 8 (1916), No. 86, pp. 141-151).—A summary and digest of data regarding the composition and fuel value of foods with respect to the selection of suitable menus for the laborer.

An experiment in the feeding of undernourished school children, Clara Schmitt (Ed. Bi-Mo., 10 (1916), No. 5, pp. 379-390).—This article gives the results of the feeding of 43 children, the food being served at the morning recess period.

The essential factors in a successful diet, E.V. McCollum (N. Y. Med. Jour., 103 (1916), No. 18, pp. 838, 839).—A summary and digest of data concerning the rôle played in nutrition by the vitamins, especially the substances known as fat-soluble A and water-soluble B, referred to in earlier work by the author.

Vitamins and complementary food ingredients, BORUTTAU (Ber. Deut. Pharm. Gesell., 25 (1915), No. 9, pp. 468-486).—The author discusses in this article the important part played by the vitamins in the deficiency diseases and the nutritional disorders of children.

Vitamins and nutritional diseases.—A stable form of vitamin, efficient in the prevention and cure of certain nutritional deficiency diseases, A. Seidell (Pub. Health Rpts. [U. S.], 31 (1916), No. 7, pp. 364-370, fig. 1).—A method is herein described for "obtaining a relatively concentrated and comparatively cheap form of vitamin suitable for studies on the prevention and cure of such human nutritional deficiency diseases as beri-beri, pellagra, infantile malnutrition, etc."

The process consists essentially in absorbing the vitamin contained in autolyzed yeast liquor by the selective action of colloidal hydrous aluminum silicate. As shown by experiments, the product is an activated solid, small doses of which exert both preventive and curative effects on pigeons receiving an exclusive diet of polished rice. The activated material is "practically tasteless and odorless, and aside from the vitamin which it contains is an absolutely inert substance which would produce no noticeable effects on passage through the body." It is estimated that 5 gm. of the activated solid per day, taken either in capsules or as an aqueous suspension, would supply the human body sufficient vitamin to prevent the occurrence of beri-beri.

The author suggests that the procedure for yeast can be used with slight modifications for estimating the vitamin content of various food products.

Observations upon the growth of young chickens under laboratory conditions, J. C. Drummond (Biochem. Jour., 10 (1916), No. 1, pp. 77-88, pl. 1, figs. 7).—Feeding experiments to determine the suitability of young chickens for the laboratory study of human deficiency diseases are reported. The results indicate that it is impossible, even by means of an adequate diet, to raise young chicks under artificial laboratory conditions to a satisfactory degree of development.

The growth of rats upon artificial diets containing lactose, J. C. Drummond (Biochem. Jour., 10 (1916), No. 1, pp. 89-102, figs. 10).—Feeding experiments with rats as laboratory animals are reported, from which the author concludes as follows:

"Lactose, prepared from milk, may contain traces of an impurity which acts as a growth-promoting accessory substance. This substance is soluble in water and alcohol, and is not destroyed by exposure to 100° for six hours.

"Before complete growth can occur in a young animal, the diet, besides being adequate as regards its proteins, carbohydrates, fats, and salts, must contain both fat-soluble and water-soluble accessory subtances. No growth is possible in the animals fed upon a purified diet which is entirely deficient in these accessory substances."

The action of Sardinian lactic acid on human metabolism, F. FIDANZA (Ann. Ig. Sper., n. ser., 25 (1915), No. 4, pp. 411-420).—The data are reported of a metabolism experiment of eight days' duration, in which a normal man ingested large quantities of a Sardinian fermented milk called "gioddu."

The author concludes that on an exclusive diet of gioddu and bread it is possible to maintain the nitrogen equilibrium of the body for only a few days. The diet did not cause diuresis nor noticeably modify the acidity of the urine. The elimination of chlorids and phosphates was not affected, but the excretion

of sulphur compounds was gradually diminished. The body weight decreased 1.5 lbs., probably owing to the monotony of the diet.

Relative toxicity of substances found in foods, A. N. Cook and Sylvanna Elliott (Jour. Indus. and Engin. Chem., 8 (1916), No. 6, pp. 503, 504).—Experimental data are reported indicating the comparative toxicity of such substances as sodium benzoate, alum, caffein, carbolic acid, etc., in the case of laboratory animals (frogs and goldfish) living in solutions of these chemicals. The authors conclude that "experiments of this nature, at least upon animals so distantly related to man, do not furnish conclusive evidence of the effects of such substances upon the human system."

The fate of inorganic nitrogen in the metabolism of the dog, W. Caldwell and H. R. S. Clotworthy (Biochem. Jour., 10 (1916), No. 1, pp. 14-25).—A number of feeding experiments with laboratory animals (dogs) are reported, which were undertaken to determine whether the protein of food may be replaced by inorganic nitrogen in the form of ammonium salts. The animals received a basal ration consisting of potatoes, dog biscuit, flour, dried milk, salt, and water during a preliminary period until nitrogen excretion was approximately constant. The dogs then received, in addition to the basal ration, known amounts of different ammonium salts, the fate of which was investigated by urine analysis.

A uniform retention of the added nitrogen was not observed nor was the extra nitrogen always excreted in the same form. Although urea was sometimes found in the urine, the authors were not convinced that it was synthesized from ammonia nitrogen. In the authors' opinion the form in which the added nitrogen is excreted depends on the ammonium salt ingested, and apparently on the ions into which the ammonium salt is dissociated.

Nitrogen metabolism during pregnancy, K. M. Wilson (Bul. Johns Hopkins Hosp., 27 (1916), No. 303, pp. 121-129, figs. 3).—Observations were made on the nitrogen metabolism in three normal pregnancies, in one case from the tenth to the fourteenth week, and in two other cases for the last 133 and 101 days of the pregnancy and also for a short time in the puerperal period.

From the data reported it is evident that "in the perfectly normal pregnant woman, storage of nitrogen begins at a much earlier period than has hitherto been supposed; possibly the organism may acquire the capacity for storing nitrogen from the very beginning of the pregnancy. In the early months this storage is far in excess of the actual needs of the developing ovum, and the excess must be added to the general maternal organism. Storage of nitrogen continues throughout the entire duration of pregnancy, being most marked during the last few weeks, when the fetal needs are at a maximum.

"The nitrogen stored is greatly in excess of the actual needs of the developing ovum, so that, apart from the amount needed for the hypertrophy and development of the genitalia and breasts, a large proportion of the nitrogen stored is added to the general maternal organism as 'Restmaterial'... [although no positive statement is made] concerning the form in which this reserve is stored.... The nitrogen capital of the maternal organism is thus increased, though the reserve supply may possibly be entirely exhausted during the puerperium and period of lactation."

There was a relative, though not necessarily an absolute, increase in the percentage of urinary nitrogen excreted as amino acids, and also a tendency for the percentage of ammonia nitrogen to increase during the last weeks of pregnancy.

Acidosis in diabetes, R. T. Woodyatt (Jour. Amer. Med. Assoc., 66 (1916), No. 25, pp. 1910-1913).—The author summarizes and discusses in this paper information regarding the underlying causes of acidosis as related to the

metabolism of protein, fat, and carbohydrate in both diabetic and nondiabetic states.

Chemical means of protection against the cold, A. Montuori and R. Pollitzer (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), II, No. 11, pp. 543-548).—The results of experiments with laboratory animals (dogs and guinea pigs) are reported, from which the authors conclude, in part, that the ingestion of alcohol or of tea does not appreciably protect the body from external cold. An infusion of coffee with the addition of a small amount of alcohol causes the body to react favorably (probably along the control nervous system).

ANIMAL PRODUCTION.

Studies on the nutritive value of straw materials, R. von der Heide, M. Steuber, and N. Zuntz (Biochem. Ztschr., 73 (1916), No. 1-2, pp. 161-192).— In these studies it was found that the crude fiber of straw is almost entirely digestible by horses, and that 1 kg. of straw material (with 20 per cent of molasses) so far as energy is concerned is of as much value as 2.55 kg. of hay or 0.92 kg. of oats. In straw feeding it was found feasible to feed 1 part of digestible protein to 14 parts of nitrogen-free material.

Chemical determination of the value of straw meal as feed material, W. Keep, F. Schröder, and B. Pfyl (Arb. K. Gsndhtsamt., 50 (1915), No. 2, pp. 232-262, pls. 6).—An account of the composition, chemical characteristics, and nutritive value of oat, wheat, rye, and barley straw meals. It is concluded that for ruminants straw meal serves a useful purpose, but that for other animals, such as swine, it has little value. As a food for man, in the form of bread, straw meal is of value.

Feeding experiments with disintegrated rye straw, A. STUTZER (Landw. Vers. Stat., 87 (1915), No. 2-3, pp. 228-236).—In feeding experiments with sheep it was found that the digestibility of disintegrated rye straw was materially increased by dampening the material with dilute acetic acid. The dampened straw had a light brown color and an agreeable odor.

On the digestibility of pine needles, A. STUTZER and W. HAUPT (*Landw. Jahrb.*, 48 (1915), No. 4, pp. 571-585).—Experiments were conducted in feeding fresh and old pine needles to sheep.

It was found that fresh needles from the tree were unsuitable for feeding purposes, and after they were pulverized they were taken only unwillingly by the sheep. When fed in conjunction with potato meal and hay the organic matter of the needles was found to be 24 per cent digestible. After extraction by alcohol the digestibility coefficient of the organic matter was 35 per cent. The increase in digestibility after extraction by alcohol was especially noticeable in the crude fiber and nitrogen-free extract. The protein of the needles was partially digestible but decreased the digestibility of the proteins of the other feeds, as in experiments where turf straw was added. The depression of digestibility was 14 per cent, and after alcohol extraction 5 per cent.

The composition of fresh needles is given as follows: Organic matter 97.83, nitrogen 1.498, fat 2.49, nitrogen-free extract 38.76, fiber 47.22, and ash 2.17, and for the old needles 91.05, 0.85, 0.15, 40.81, 44.78, and 8.95, respectively.

Experiments with sphagnum turf as a feeding stuff, A. Stutzer (Landw. Vers. Stat., 87 (1915), No. 2-3, pp. 215-227).—In feeding experiments with sheep the author found that the dampening and disintegrating of sphagnum turf with dilute hydrochloric acid, which was later neutralized with sodium carbonate, materially increased the digestibility.

Cattle feeding.—XI, Winter steer feeding, 1914—15, J. H. SKINNER and F. G. King (Indiana Sta. Bul. 183 (1915), pp. 857–891, fig. 1; pop. ed., pp. 8, fig. 1).—In these experiments seven lots of 10 steers each were fed 150 days, all the lots except lots 1 and 6 receiving shelled corn and 2.5 lbs. daily per 1,000 lbs. live weight of cotton-seed meal, and lot 1 receiving shelled corn, ground soy beans, 2.5 lbs. daily per 1,000 lbs. live weight, corn silage and oat straw; lot 2, clover hay; lot 3, alfalfa hay; lot 4, corn silage and clover hay; lot 5, molasses, corn silage, and clover hay; lot 6, shelled corn, molasses feed, corn silage, and clover hay; and lot 7, corn silage and alfalfa hay. Ten head of hogs followed each lot. The work was in continuation of that previously noted (E. S. R., 33, p. 371).

Part 1 is a comparison of corn silage and leguminous hay v. leguminous hay for fattening steers, involving lots 2, 3, 4, and 7.

"The addition of 24.94 lbs. of corn silage to a ration of shelled corn, cotton-seed meal, and clover hay decreased the average grain consumption 4.09 lbs. daily per head and the hay consumption 8.6 lbs. daily per steer. The addition of 28.36 lbs. of corn silage to a ration of shelled corn, cotton-seed meal, and alfalfa hay decreased the average grain consumption 4.09 lbs. daily per head and the hay consumption 10.23 lbs. daily per steer. The addition of corn silage to a ration consisting of shelled corn, cotton-seed meal, and clover hay decreased the rate of gain, while in a ration containing alfalfa hay the gains of the cattle were increased by the addition of corn silage. Corn silage in the ration decreased the cost of gain 4 cts. per 100 lbs. when clover hay was fed and \$3.16 per 100 lbs. when alfalfa hay was fed. The addition of corn silage to the ration had on the average no effect on the finish of the cattle. The addition of corn silage to the ration decreased the loss per steer \$2.80 when clover hay was fed and \$12 when alfalfa hay was fed."

Part 2 is a comparison of ground soy beans v. cotton-seed meal for fattening steers, involving lots 1 and 4. The cattle fed ground soy beans made the more rapid and more economical gains and attained a higher finish. There was a greater pork production in the lot receiving cotton-seed meal.

Part 3 is a comparison of clover hay v. alfalfa hay as roughage for fattening steers, involving lots 2, 3, 4, and 7. The cattle fed shelled corn, cotton-seed meal, and clover hay ate the same quantity of corn and very nearly the same quantity of hay as the cattle fed shelled corn, cotton-seed meal, and alfalfa hay. Cattle fed shelled corn, cotton-seed meal, clover hay, and corn silage consumed the same quantity of grain but more hay and less silage than those fed a ration in which alfalfa hay was used instead of clover. Cattle fed clover hay as the only roughage made more rapid gain than those fed alfalfa hay. Cattle fed clover hay and corn silage made less rapid gains than those fed alfalfa hay and corn silage. Gains were more economical with clover hay than with alfalfa hay as roughage, and less economical with clover hay and corn silage than with alfalfa hay and corn silage as roughage. Cattle fed a ration of shelled corn, cotton-seed meal, and clover hay returned a loss, including pork, of \$10.26 per steer against a loss of \$13.07 when alfalfa hay replaced clover hay. A ration of shelled corn, cotton-seed meal, corn silage, and clover hay returned a loss, including pork, of \$7.46 per head as compared with a loss of \$1.07 per head when clover hay was replaced by alfalfa hay.

Part 4 is a comparison of cane molasses v. mixed molasses feed as supplements to rations for fattening cattle, and involving lots 4, 5, and 6. It was found that the substitution of a small quantity of feeding molasses for an equal quantity of corn in a ration of shelled corn, cotton-seed meal, clover hay, and corn silage had no appreciable effect on the consumption of con-

centrates but greatly increased the consumption of silage. The feeding of a proprietary molasses feed instead of cotton-seed meal had very little effect on the appetites of the cattle. The addition of molasses to the ration increased the rate of gain; the use of the molasses feed instead of cotton-seed meal resulted in a smaller rate of gain. Cattle fed a ration of shelled corn, cotton-seed meal, corn silage, and clover hay returned a loss of \$7.46 per steer, including pork; cattle fed a similar ration with a part of the corn replaced by feeding molasses returned a loss of \$6.19 per head; cattle fed a ration of shelled corn, proprietary molasses feed, corn silage, and clover hay returned a loss, including pork, of \$12.91 per steer.

Dual purpose cattle, K. J. J. MACKENZIE (Jour. Bath and West and South. Counties Soc., 5. ser., 10 (1915-16), pp. 71-77).—A general discussion of the economical advantages of dual purpose cattle, with data on feeding trials showing the gains and profits made by this type of steer.

Sheep feeding.—V, Fattening western lambs, 1914–15, J. H. SKINNER and F. G. King (Indiana Sta. Bul. 184 (1915), pp. 893–912, fig. 1; pop. ed., pp. 7, fig. 1).—In these experiments nine lots of 25 choice Idaho lambs each were fed 90 days as follows, the first eight lots being fed in an open shed and the ninth lot in a barn: Lot 1, shelled corn and cotton-seed meal, 7:1, and corn silage; lot 2, shelled corn and oats, 2:1, and clover hay and corn silage; lot 3, shelled corn and clover hay; lot 4, shelled corn and alfalfa hay; lot 5, shelled corn and cotton-seed meal, 7:1, and oat straw and corn silage; lot 6, shelled corn, clover hay, and corn silage; lot 7, shelled corn and cotton-seed meal, 7:1, and clover hay and corn silage; lot 8, shelled corn and cotton-seed meal, 4:1, and clover hay and corn silage; and lot 9, shelled corn, clover hay, and corn silage. The work was in continuation of that previously noted (E. S. R., 33, p. 374).

Part 1 is a comparison of corn silage and clover hay as roughage for fattening lambs, involving lots 3 and 6. The addition of corn silage to the ration of shelled corn and clover hay did not affect the grain consumption, but 1.38 lbs. of silage replaced 0.69 lb. of clover hay in the daily ration per lamb. Lambs fed the ration of shelled corn and clover hay gained 27.4 lbs. per head in 90 days, as compared with 29.4 lbs. per lamb when corn silage was added. The addition of corn silage to the ration reduced the cost of gain 1.21 cts. per pound, slightly increasing the selling value of the lambs, and increased the profit 40 cts. per head.

Part 2 is a comparison of corn silage alone v. corn silage and dry roughage for fattening lambs, involving lots 1, 5, and 7. Lambs receiving no dry roughage did not consume so large quantities of grain as those fed some dry roughage. There was no difference in grain consumption between lambs fed silage and oat straw for roughage and those fed silage and clover hay for roughage. The silage consumption was somewhat in proportion to dry roughage consumed, the largest quantity being eaten when no dry roughage was fed and the smallest quantity when clover hay was fed. Gains made by lambs fed silage alone for roughage were 23 lbs. per head in 90 days at a cost of 6.74 cts. per pound; 27 lbs. at a cost of 6.21 cts. per pound when silage and oat straw were fed; and 30.1 lbs. at a cost of 7.37 cts. per pound when silage and clover hay were fed. The lambs in lot 1 were valued at 8.4 cts. per pound and returned a profit of 92 cts. per head; in lot 5, at 8.5 cts. per pound and returned a profit of \$1.21 per head; and in lot 7, at 8.75 cts. per pound and returned a profit of \$1.15 per head.

Part 3 is a comparison of clover hay v. alfalfa hay as roughage for fattening lambs, involving lots 3 and 4. The lambs of the two lots are exactly the same quantities of both grain and hay, but the lambs fed shelled corn and clover

hay gained 27.4 lbs. per head as compared with 25.7 lbs. by lambs fed shelled corn and alfalfa hay. Larger quantities or feed per pound gain were required by the lambs fed alfalfa hay than by those fed clover hay. In lot 3, the gains cost 8.62 cts. per pound and the lambs were valued at 8.6 cts. per pound and returned a profit of 64 cts. per head. In lot 4, the gains cost 9.8 cts. and were valued at 8.5 cts. per pound, with a profit of 26 cts. per head.

Part 4 treats of cotton-seed meal as a supplement to rations for fattening lambs, involving lost 6, 7, and 8. The addition of cotton-seed meal to a ration of shelled corn, clover hay, and corn silage had practically no effect on the appetites of the lambs for either grain or roughage, but increased the rate of gain made by the lambs, slightly decreased the feed required to make a pound of gain, and increased the selling value of the lambs. The lambs in lot 6 made gains at a cost of 7.41 cts. per pound and returned a profit of \$1.04 per head; those in lot 7 made gain at a cost of 7.37 cts. per pound and returned a profit of \$1.15 per head; and those in lot 8 gained at a cost of 7.17 cts. per pound and returned a profit of \$1.32 per head.

Part 5 treats of the value of oats for lambs, involving lots 6 and 2. The addition of oats to a ration of shelled corn, corn silage, and clover hay caused a decrease in grain and hay consumption. Gains were more rapid when no oats were fed. The cost of gain was 0.38 ct. per pound greater and the profit was 17 cts. per head less when oats were fed.

Part 6 is a comparison of open shed v. barn as shelter for fattening lambs, involving lots 6 and 9. The lambs fed in a well-ventilated barn ate the same amount of feed and made the same gains in weight as those fed in an open shed, but were of softer flesh and were valued at 0.1 ct. per pound less. The profit per lamb was 94 cts. per head in the barn as compared with \$1.04 per head in the open shed.

Wool studies: Washing before shearing; time of shearing, J. W. Hammond (Ohio Sta. Bul. 294 (1916), pp. 309-322, figs. 3).—The object of this experiment was to determine the influence of washing sheep on the yield of grease and of scoured wool and on the rate of gain made by the sheep, and the influence of the time of shearing on the yields of grease and of scoured wool and on the rate of gain made by the sheep.

The experiment extended over a little more than two years, so that during its progress three clips of wool were removed, in 1911, 1912, and 1913. The treatment of the four lots, of 25 Merino sheep each, with respect to washing and time of shearing, was as follows: Lot 1, washed, shorn about April 12; lot 2 unwashed, shorn about April 12; lot 3, washed, shorn about June 1; and lot 4, unwashed, shorn about June 1.

A short time before being washed in 1913 one-half of the sheep in lots 1 and 2 were shifted from one lot to the other, and a similar shift was made in lots 3 and 4.

The sheep were washed in a stream of sufficient swiftness to supply an abundance of clean water. Each sheep was held in the stream separately and the dirt squeezed out of the wool by hand. An attempt was made to do a thorough job of washing, but, because of the density of the fleeces and the large amount of yolk they carried, it is probable that the washed wool still contained more foreign matter than is usually contained in washed wool from more open-wooled sheep. After the sheep were washed, from seven to ten days were allowed to intervene before they were shorn, to allow the wool to dry out thoroughly.

The scouring was done by the emulsion process, similar to that used commercially. The wool was put through three scouring liquors containing potash soap and potassium carbonate, of gradually diminishing strengths, and finally

through a rinse of clear, warm water. The wool was dried to a constant weight at a temperture of 150° F. both before and after scouring, to overcome any differences in moisture content that might exist on different days.

With respect to the effect of washing it was found that washed sheep produced 1.49 lbs. less grease wool per head when shorn April 12 and 2.64 lbs. less per head when shorn June 1 than did unwashed sheep shorn on the same dates. Washing the sheep had practically no effect on the amount of scoured wool produced or on the rate of gain made by the sheep. Wool shorn June 1, both washed and unwashed, shrank more in scouring than did wool shorn April 12. The data yielded by this experiment indicate that, in many cases at least, not sufficient premium is paid for washed wool to cover the cost of washing and the loss in weight of the wool. Since washing sheep does not improve the quality of the wool fiber and does not diminish the cost of scouring, the practice is not beneficial to the manufacturer.

As regards early v, late shearing, washed sheep shorn April 12 produced more grease wool than did washed sheep shorn June 1, while unwashed sheep shorn April 12 produced less grease wool than did unwashed sheep shorn June 1. This indicates that between these two dates there was an increase in weight of fleece due to the accumulation of a greater proportion of yolk or other foreign matter in the wool. Sheep shorn April 12, both washed and unwashed, produced slightly more scoured wool than did sheep shorn June 1. Sheep shorn April 12 made slightly greater gains than did sheep shorn June 1.

Trials with alfalfa as a hog feed. Some pasture crops for hogs, W. H. Peters and D. J. Geiken (North Dakota Sta. Circ. 13 (1916), p. 8).—Three groups of three lots each of three and four pigs each, group 1, 3-month-old pigs, group 2, 7-month-old pigs, and group 3, mature brood sows, were fed from January 9 to March 13, 1915, with the following results:

Feed consumed, gains made, and cost of gains in hog-feeding tests.

Group.	Lot.	Feed used.	Gain per head per day.	Grain per pound of gain.	Cost per pound of gain.	Sav- ing in cost per pound of gain.
			Pounds.	Pounds.	Cents.	Cents.
1	1	Barley 629, shorts 318, tankage 105 lbs	0.80	5.30	5. 3	
1	2	Barley 526, shorts 263, tankage 88, dry alfalfa,	. 78	4.47	4.8	0, 5
1	3	147 lbs Barley 541, shorts 270, tankage 90, steamed al-	. 10	2. 2/	1.0	0. 5
•		falfa 175 lbs	. 80	4,50	4.9	.4
2	1	Barley 922, shorts 461 lbs	. 66	8, 32	8.3	
2	2	Barley 818, shorts 409, dry alfalfa 173 lbs	.77	6. 25	6.6	1.7
2 2 2 3	3	Barley 874, shorts 437, steamed alfalfa 235 lbs	1.00	5.14	5. 6	2.7
3	1	Barley 926, oats 463 lbs	1.08	6.78	6.8 7.5	
3	2	Barley 949, oats 474, dry alfalfa 507 lbs	1.18	6, 42		.7
3	3	Barley 790, oats 395, steamed alfalfa 410 lbs	1.47	4.30	5.0	1.8
				1		

For the three lots where dry alfalfa hay was used it was put through a straw cutter and cut into one-half-inch lengths, and was fed by placing the dry hay in the troughs after the grain had been eaten at each feeding time. With the three lots where steamed hay was used it was put through the cutter, and then steamed for an hour or so before feeding by running live steam into a large can containing hay.

The results indicate that in order to get hogs started eating alfalfa hay in winter it is necessary to limit the grain to such an extent that the hogs must eat hay or go hungry. When handled in this way they will take very readily to the hay, and a limited amount of hay can be fed satisfactorily, securing as

good results and at less cost than where grain alone is fed. The greatest advantage to be gained in feeding hay in winter is a saving of grain and the lowering of the cost of feeding.

In another experiment, during the winter of 1915-16, 40 sows were fed alfalfa hay with a limited grain ration, while 10 others were fed the same grain ration without alfalfa. The idea was to get the sows to eat all the alfalfa they would and to feed just enough grain to keep them in satisfactory breeding condition. Observation of the sows was made during the winter months and during the month of March while they were farrowing. It was found possible to replace one-third of the grain ration for broad sows with alfalfa hay, 1.04 lbs, of alfalfa hay replacing 1 lb. of grain. The feeding of alfalfa afforded an excellent means of getting the sows to take more exercise than they do when fed grain alone. No trouble was experienced by any of the sows in farrowing, and the sows fed alfalfa hay farrowed as large, strong, and uniform litters of pigs as did the sows not receiving it. The sows fed alfalfa appeared to milk better and nurse their pigs a little better than did those not receiving hay. The results obtained in this trial indicate that it is practical and advisable to feed as much alfalfa hay to brood sows in winter as they will eat, so regulating the additional grain ration as to keep the sows in proper condition.

There is included a general discussion of alfalfa, sweet clover, rye, oats, barley, rape, and Canada field peas as pasture for hogs.

Concentrates for growing chicks and for laying stock, M. A. Jull (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 9, pp. 66-70).—In experiments at Macdonald College three lots of 65 White Leghorn pullets were fed a basal ration of bran, corn meal, middlings, and oatmeal, 2:1:1:1, lot 1 receiving fish scrap and lot 2 a prepared mineral food in addition.

The birds in the fish-scrap pen ate 2 lbs. more feed than those in the check pen. Those in the prepared mineral-food pen ate the same amount as the check pen. The prepared mineral- and fish-scrap-fed pens laid about an equal number of eggs, the check pen not laying half as much as the other two pens.

In a second test to determine the value of dry ground-bone meal, fish scrap, a prepared mineral food, and beef scrap for growing chickens and winter egg production five pens were fed a basal ration as above with the respective supplements. The final order of merit, considering food consumed, weights, eggs laid, and profits realized, was beef scrap, prepared mineral food, fish scrap, bone meal.

This work brings out very strongly the value of mineral elements in a soluble condition in making an economical use of the feeds consumed in digestion, for in the second test less feed was taken to produce 1 lb. gain in live weight in the case where prepared mineral food was fed than with any of the other concentrates. Still, beef scrap ran the prepared mineral food very close in this respect, which may be due to the fact that the great success of animal feeds for growing chickens is because of the mineral elements found in them. The bone-meal concentrate was found in both tests to be of little nutritive value for young chickens, which confirms the belief that its mineral elements are in an unavailable state, especially for young poultry. It was found in the first test that a comparatively small percentage of mineral matter upset the birds, which made it imperative to drop the amount of prepared mineral food fed from 10 per cent to 5 per cent of the mash.

The birds receiving fish scrap did not lay tainted eggs, nor did their meat possess an unfavorable taste. Therefore, there is believed to be no danger from this source when 10 per cent of fish scrap is fed in the mash.

Skim milk for laying hens, H. R. Lewis (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 9, p. 72).—In experiments conducted at the

New Jersey Experiment Stations two pens of 100 White Leghorn pullets each were fed the regulation ration, pen 1 receiving in addition an unlimited amount of sour skim milk.

Pen 1 laid during the first 12 months 12,044 eggs, or an average production of 34.4 per cent. The value of these eggs on the wholesale market was \$375.04. The food cost, including skim milk, was \$116.37, leaving a net profit above all food consumed of \$258.67. Pen 2 laid during the first 12 months 8,382 eggs, or an average percentage production of 25.76, with a resulting value of eggs produced of \$256.14. The cost of all food consumed in this pen was \$99.21, leaving a resulting profit, above food, of \$156.93.

In addition to this study four other tests with younger and older birds and with birds of different breeds were run simultaneously. The results of all these studies verify the differences shown in this particular instance, although in no case was the difference quite so pronounced. The conclusion reached from a careful analysis of these and other records of similar nature are as follows:

Sour skim milk has a very definite place in the nutrition of laying hens, being a splendid source of protein food, the element so necessary for the production of eggs. The returns measured in number of surplus eggs produced indicate that the sour skim milk has nearly five times the value paid for it. The feeding of sour milk kept the birds in better physical condition, lowering mortality and keeping them practically free from disease. It slightly increased the consumption of other parts of the ration, probably because the skim milk kept the digestive organs in splendid running order so that they were able to handle larger amounts, and it is thought that on a commercial basis this factor would appear more strongly than it did in this somewhat limited experiment. Egg producers can afford to pay from 40 to 80 cts. per 100 lbs. for skim milk. It can be fed in open pans, thus necessitating very little labor.

External characters as indications of egg production, O. B. Kent (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 3, pp. 63. 64).—A study of the theory that late layers are late molters and that late molters molt rapidly gave a correlation of over 0.5 with a probable error of \pm 0.02. The relation held true regardless of whether it was the first, second, third, or fourth year of production. None of the birds that were more than half way through their molt about October 1 were high producers and only a few late molters were low producers. Contrary to popular opinion the late molters molt rapidly and begin to lay as soon or sooner than the early molters. The medium molters begin to lay slightly ahead of the late or early molters. A very sightly better correlation was found between color of shank and egg production than between molting and egg production. This degree of pigmentation elsewhere is also an indication.

The health of the bird, as shown by the condition of the comb, is deemed a fair indication of egg production. When the comb is full-sized, red, pliable, and somewhat slippery the bird is usually laying. The comb shrinks, becomes hard, light-colored, and rough as the bird stops laying. A series of observations made between pliability of comb and egg production gave a correlation of over 0.3 with a probable error slightly greater than \pm 0.02. The pliability of the comb indicates whether the bird is laying at the time. Late laying tends to give high egg production.

The smoothness, pliability, and oiliness of the skin are also indications of egg production. A laying bird has a softer, smoother feeling than a nonlaying one.

The abdomen is a very good indicator of egg production. A bird, due to the yolks developing in the ovary and the increase in size of the oviduct, swells out its abdomen in preparation for a laying period. It makes little difference whether the distance between the pelvic arches, from the keel bone to the pelvic

arches, or from the keel bone to the base of the tail is used as a basis of selection, as these parts are very closely correlated in size. After a bird has stopped laying or as it gets ready to stop the abdomen shrinks. The actual distance between these parts depends on the size of the bird and the size of her egg, as well as the number of eggs about to be laid. The system is of value in telling what the bird may do for the next two or three weeks, or, by knowing that the hird is laying at certain times of year, it indicates high or low production.

Occurrence and significance of Bacterium pullorum in eggs, L. F. RETTGER (Jour. Amer. Assoc. Instr. and Invest. Poultry Husb., 2 (1916), No. 3, pp. 62, 63).—The material reported is noted from another source (E. S. R., 35, p. 264).

DAIRY FARMING-DAIRYING.

The mineral metabolism of the milch cow; first paper, E. B. Forbes, F. M. Beegle, et al. (Ohio Sta. Bul. 295 (1916), pp. 323-348).—Two groups of 3 Holstein-Friesian cows each were fed during three periods of 19 or 20 days each, with 10-day intervals between periods, as follows: During the first period, group 1, corn, cotton-seed meal, timothy hay, and corn silage, and group 2, corn, cotton-seed meal, and clover hay; second period, group 1, corn, cotton-seed meal, clover hay, and corn silage, and group 2, corn, distillers' grains, clover hay, and corn silage; third period, group 1, corn, linseed meal, clover hay, and corn silage, and group 2, corn, gluten feed, clover hay, and corn silage.

It was found that liberal milk production on common practical winter rations fed in quantities sufficient to maintain the live weight and to cause regular nitrogen and sulphur storage caused consistent losses of calcium, magnesium, and phosphorus from the cows' skeletons. These losses occurred in spite of liberal supplies of these nutrients in the food. The limited response of the cows to an increase in the intake of these elements indicated that their utilization of these nutrients on a profitable plane of food consumption and milk production was surprisingly inefficient. The cause of this inadequate utilization of minerals, especially calcium, and the possibility of preventing losses of these nutrients stand in need of further investigation.

An extensive metabolism of silicon was demonstrated. An excess of inorganic acids over inorganic bases in a ration, due largely to the silicon of timothy hay, caused an acid reaction and an increase in the ammonia of the urine.

No important specific effects were observed of the nitrogenous concentrates, cotton-seed meal, linseed meal, gluten feed, and distillers' grains, on the digestibility of the rations in which they were fed.

The results of this study indicate that special attention should be given to the calcium, magnesium, and phosphorus contents of the rations of heavily-producing cows in order that the loss of these elements from the skeleton may be kept as low as possible. A liberal supply of foods which are rich in these elements should be allowed after the cow has ceased to produce abundantly, during the latter part of the period of lactation, in order to refund previous overdrafts before the birth of the next calf.

Silage made from oats and tares as a food for milking cows, A. W. Oldershaw (Jour. Bd. Agr. [London], 23 (1916), No. 3, pp. 224-229).—In this experiment six cows fed a daily ration of concentrated foods and chaff, supplemented by 60 lbs. of silage made from oats and tares, gave approximately the same quantity of milk as six cows fed a similar quantity of concentrated foods and chaff, supplemented by a daily ration of 60 lbs. of mangolds.

Value of the seven-day test, T. E. Woodward (Hoard's Dairyman, 51 (1916), No. 25, p. 960, fig. 1).—In a study of data collected from the advanced registry

records of the Holstein-Friesian Association comparing the reliability of sevenday and yearly tests, the author found that in general the yearly production varied with the record for seven days, but not in the same proportion. For instance, the cows yielding from 10 to 12 lbs. of fat in seven days gave on the average 423.71 lbs. in 365 days, while cows yielding twice as much in seven days gave only about one-half more in the course of a year. This indicates that the cows which produce the best during the first few weeks do not hold up so well later as do those which produce less during the early part of their lactation period. It appears that the higher the seven-day record the greater the variation in the 365-day test and the less accurate the seven-day test becomes as an indicator of the true production.

Influence of temperature on the proteolytic activity of lactic ferments, C. Gobini (Atti R. Acad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), II, No. 8, pp. 369-376; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 1, p. 143).—The author has already pointed out (E. S. R., 34, p. 76) a difference in the organoleptic properties of peptonized whey produced by the same lactic ferment but developed at different temperatures. This difference led to the presumption of differences in the products of caseolysis.

The present investigations are a new analytic contribution to the demonstration already given by him as to the favorable influence exerted by low temperatures on the proteolytic activity of milk ferments. They further indicate that the lactic ferments should be especially studied in cultures kept at low temperatures. The number of lacto-proteolytic ferments capable of peptonizing casein in an acid medium is enlarged, and it is concluded that the optimum temperature is not the same for all the functions of a given microorganism.

The proteolytic indexes have been collected by the author in a table, and show the possibility of verifying, also analytically, not only the quantitative differences but also the qualitative differences in the proteolytic products of lactic ferments according to the temperature.

In the explanation of the greater caseolytic activity at low temperatures it must be considered that at this temperature the lactic ferments attack lactose more slowly. The milk attains later than at high temperatures a degree of acidity capable of attenuating and stopping the development of the bacteria, which thus can continue for a greater length of time to attack casein.

Experiments in Sweden on the prolonged pasteurization of milk, C. BARTHEL (K. Landtbr. Akad. Handl. och Tidskr., 54 (1195), No. 7, pp. 610-648, figs. 2; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1915), No. 1, pp. 143-146).—Trials with the "holder" process of pasteurizing conducted in Sweden have proved very satisfactory. It was found that milk pasteurized for from 20 to 30 minutes at 145° F. has no "cooked" taste, although this becomes noticeable at 149°. The cream also rises as readily in milk pasteurized at 145° as in unheated milk, but after pasteurizing at 149° it rises more slowly. Heating to 145° does not affect the protein or the soluble phosphates, but here again the influence of a temperature of 149° begins to make itself felt. The enzyms remain intact at 145° with the exception of amylase, which is destroyed at a relatively low temperature.

The experiments showed that pasteurized milk keeps from one to two days longer than ordinary milk, according to the temperature at which it is kept. The effect of pasteurization in destroying bacteria is also very satisfactory. When the milk after being heated is reinfected by the ordinary lactic ferments it becomes acid in the usual way, but naturally more slowly than unpasteurized milk.

The prolonged pasteurization of milk as carried out in the dairy industry, viz, heating for from 20 to 30 minutes at from 140 to 147.2° in apparatus maintaining it in continual motion, is deemed sufficient to remove all danger of the conveyance of tuberculosis by means of milk.

Studies on Swedish Emmental cheese and large-eyed Swedish cheese (Herrgårdsost), L. F. Rosengren and E. Haglund (K. Landtbr. Akad. Handl. och Tidskr., 53 (1914), No. 7, pp. 485-526, figs. 8).—In these studies a marked difference was found between the Swedish Emmental and Herrgård cheese: Much the larger amount of amino acids was formed in the Swedish Emmental cheese during ripening.

In both cheeses the volatile fatty acids were formed mostly from acetic and propionic acids. The content of such acids was generally smaller in cheese with weak eye-formation than in cheese with strong eye-formation. The sweet-bitter cheeses contain an abnormal quantity of butyric acid. A large amount of salt decreased the content of volatile fatty acids substances in the Swedish Emmental cheese, and the addition of saltpeter decreased the content in both cheeses, especially the propionic acids. The addition of saltpeter to the milk often gave a taste of saltpeter to the cheese and spoiled its color, but can control too rapid fermentation.

Cheese making, C. L. STAHL (Va. Dairy and Food Div. Bul. 59 (1916), pp. 27, figs. 7).—This deals with methods and costs of cheese making.

VETERINARY MEDICINE.

Annual report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, for the year 1914-15, A. SMITH and P. J. Kerr (Ann. Rpt. Bengal Vet. Col. and Civ. Vet. Dept., 1914-15, pp. 4+III+7+VIII+4).—This is the usual annual report (E. S. R., 32, p. 678).

Annual report on the Punjab Veterinary College, Civil Veterinary Department, Punjab, and the Government Cattle Farm, Hissar, for the year 1914-15, Pease, J. Farmer, and R. Branford (Ann. Rpt. Punjab Vet. Col. and Civ. Vet. Dept., 1914-15, pp. III+2+17+XVII).—This is the usual annual report (E. S. R., 32, p. 272).

The utilization of sucrose and the inverting power of the blood serum after parenteral administration of sucrose, S. Kuriyama (Jour. Biol. Chem., 25 (1916), No. 3, pp. 521-547).—"In correspondence with earlier observations... sucrose, administered parenterally to dogs, was not eliminated quantitatively in the urine. The amount recovered varied considerably, averaging 76 per cent when sucrose was injected in doses of from 0.4 to 0.9 gm. per kilogram of body weight. The elimination was usually concluded within 24 hours. The degree of utilization was essentially the same for the different paths of parenteral introduction of the sugar. The apparent utilization of a small part of the sucrose, as judged by its failure to be excreted by the kidneys, may be due to the presence or rapid production of sucrose in the blood....

"Experiments in vitro showed that the inverting power of active yeast or intestinal extracts was not lost in the presence of defibrinated blood or serum, although it was considerably decreased. Addition of acid facilitated the invertin reaction and therefore was carried out in some of the experiments with serum.

"That the activity of sucrase is retained in the circulation itself was shown by the results of injecting solutions of active yeast invertin; for under such conditions injected sucrose failed to reappear in as large amounts as usual. The better utilization was not due to any failure of the kidney functions in excreting sucrose. The invertin can be demonstrated in the blood after injection of such an enzym extract. It soon disappears from the circulation, and can no longer be detected in the serum at the end of from 20 to 24 hours. The better utilization of sucrose thereupon does not continue to be manifested. Invertin was not excreted into the urine. . . .

"Examination of the serum of dogs and rabbits after repeated parenteral injections of sucrose in both small and large doses has uniformly failed . . . to demonstrate the presence of invertin in amounts detectable by the methods employed. Glucose was likewise unaltered by the sera of the animals examined."

See also a previous note by Röhmann (E. S. R., 34, p. 675.)

The intravenous injection of magnesium sulphate for anesthesia in animals, J. Auer and S. J. Meltzer (Jour. Expt. Med., 23 (1916), No. 5, pp. 641-653).—Experimental data submitted show that "by the intravenous injection of fourth-molar magnesium sulphate into dogs at a certain rate, a stage can be reached where the abdominal walls are completely relaxed and when section of the abdomen and stimulation of sensitive parts of the parietal peritoneum do not produce pain or elicit any reaction of the animal. At the same time spontaneous respiration may still be maintained within normal limits and the lid reflex be fair or even normal. In this stage intratracheal intubation for artificial respiration can be easily accomplished. This stage may be attained in 12 to 14 minutes when the rate of injection is about 3 cc. per minute.

"When this stage is once attained the rate of injection should gradually be reduced, otherwise, sooner or later, spontaneous respiration will be abolished, and by a further maintenance of the rate of injection all the skeletal muscles may become paralyzed. When the injection of magnesium is continued for a longer period the paralytic effects of the magnesium injection will set in, even when administered at a slow rate.

"The paralysis of the respiratory function is readily met by intrapharyngeal insufflation, which is easily executed even without training in this procedure, or by the method of intratracheal insufflation, if executed by one trained in its management. When the respiration of the animal is accomplished by insufflation, the paralytic effect of the magnesium may be abolished fairly rapidly by an intravenous injection of about 10 cc. of an eight-molar calcium chlorid solution; or it may disappear slowly, after the infusion of the magnesium solution is discontinued for some time. The latter mode of disappearance may be favorably accelerated by an intravenous infusion of 60 to 100 cc. of a fourth-molar solution of sodium sulphate."

It is indicated that the production of anesthesia by the intravenous injection of magnesium should not be undertaken unless an apparatus for intrapharyngeal insufflation is at hand. Calcium chlorid should not be employed in cases in which the subject shows cardiac insufficiency, nor should the method of producing the anesthesia be used in such instances.

Some fallacies regarding phenol, M. I. WILBERT (*Pub. Health Rpts.* [U. S.], 31 (1916), No. 17, pp. 1046-1051).—Experiments in which the germicidal value of mixtures of phenol and ethyl alcohol and of phenol and glycerin was determined are reported, together with experiments on the effect of ethyl alcohol or glycerin on the toxicity of phenol, as shown by inoculations into white mice.

From the experimental work it is concluded that "the addition of ethyl alcohol to phenol not only increases the solubility of phenol in water, but also increases rather than diminishes the antiseptic value of the resulting solution. Ethyl alcohol can be used to advantage as a substitute for glycerin in making antiseptic solutions of phenol. . . . The addition of ethyl alcohol to solu-

tions of phenol in water does not in any way inhibit the toxic action of phenol, but rather tends to facilitate absorption and thus hasten death."

The conditions and characters of the immunity produced in the guinea pig by instillation of horse serum into the nose, H. Sewall and C. Powell (Jour. Expt. Med., 24 (1916), No. 1, pp. 69-86).—The results of the experimental work submitted are summarized as follows:

"Normal guinea pigs treated by from four to six instillations of horse serum into the nose on alternate days become either hypersensitive or refractory to an intravenous injection of 0.38 cc. of serum given 16 days after the last instillation. If the amount of serum in each instillation is as much as 0.2 cc., anaphylactic death is caused by the toxic injection. If the amount of serum in each instillation is reduced to 0.04 cc., the first intravenous injection is without marked effect, and a second injection and subsequent injections of the same amount of antigen are well tolerated in about half the cases.

"The effect produced by a given dose of serum, whether protective or anaphylactic, depends probably upon the extent of contact with the mucous membrane of the nose. Guinea pigs which, after nasal treatment, have become tolerant to a definite maximum intravenous injection of the antigen appear to increase the degree of their tolerance, at least up to a resting period of more than four months. The same does not hold in animals immunized by the peritoneal route.

"The first two or three instillations of a series probably determine the biologic character, whether of hypersensitiveness or hyposensitiveness, of reaction toward the serum. It is probable that, contrary to the case in parenteral sensitization, hypersensitiveness and protection, respectivly, set up by nasal instillations and not followed by parenteral injections, gradually disappear in about 50 to 100 days. We have failed in attempts to eliminate hypersensitiveness, due to subcutaneous injection of serum, by nasal instillations which would protect the normal animal from the development of anaphylaxis."

From the results it is indicated that "the peculiar value of rest in the treatment of infection depends upon the fact that absorption of minimal amounts of toxic matter produces a positive protective reaction in the organism, while the absorption of larger amounts renders the cells hypersensitive. The biologic response to the intoxication is probably chiefly determined within the first 48 hours of absorption, and, therefore, rest at the beginning of an infective process has preponderant prophylactic value."

It is indicated that the principles of prophylaxis evolved under these relatively simple conditions should be applied in the study of infectious diseases.

Immunity conferred by the transfer of immune and of mixed immune and sensitized serums, H. Sewall, W. C. Mitchell, and C. Powell (Jour. Amer. Med. Assoc., 67 (1916), No. 2, pp. 95-98).—The work reported was undertaken to discover, if possible, whether the blood serum of guinea pigs, rendered immune to considerable intravenous injections of horse serum by a preceding course of nasal instillation of the serum, has a different biological effect from the serum of highly sensitized animals when injected intraperitoneally into normal guinea pigs.

It is deemed that the experimental results reported, taken in connection with earlier findings (see the previous abstract) justify the following tentative conclusions:

"A foreign protein injected into a normal animal sets up reactive processes leading to the formation, in this field, of two antibodies having opposite characters; one tends to induce, and the other to avert, the establishment of the anaphylactic state. Serum containing an excess of the anaphylactic antibody, when transferred to normal animals, renders them, as is well known, passively

anaphylactic. Serum containing a sufficient excess of the 'protective' antibody, when transferred to normal animals, initiates in them the phenomena of active immunity. Mixtures of the two types of serum seem still more effective in conferring immunity. The metabolism of the body cells is specifically modified by combination with these antibodies in such a way as to give rise to hypersensitization on the one hand or to active immunity on the other."

Serum antitrypsin during inanition.—Studies on ferment action, XIX, J. W. Jobling and W. Petebsen (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1915), No. 3, pp. 219-234, figs. 5).—During the fasting period a marked decrease in the amount of serum antitrypsin is evident. The lowering of the antitryptic titer is accompanied by an increase of nonprecipitatable nitrogen in the serum, which indicates a protein intoxication. Such periods of intoxication are followed by a rise in antitryptic titer. Through this increase of antitrypsin a further protease action of the serum can be overcome. The premortal nitrogen excretion very shortly follows the period of lowest antitryptic titer and subsequent increase in nonprecipitatable nitrogen in the serum.

Death by starvation is caused by an intoxication from split protein products. The experiments reported confirm the conclusion of Schulz that the influence of the metabolic processes during the starvation period is dependent not only on the quantity of fat but also on an autointoxication resulting from the altered balance of the ferment-antiferment system. A marked leucocytosis is noted in the dog at such times of intoxication. Diluting the serum during intoxication does not prevent death.

Protein metabolism seems to be markedly influenced by the amount of antitrypsin in the blood. If the titer is high little nitrogen is excreted. If the titer is low, however, a relatively large excretion takes place.

See also a previous note (E. S. R., 32, p. 678).

The occurrence of the coagulation reaction in anaphylactic shock and in poisoning with anaphylatoxin, L. Herschfeld and R. Klinger (Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 24 (1915), No. 3, pp. 235-257).—In the blood of animals (rabbit, guinea pig, and dog) which had been actively or passively sensitized a positive coagulation reaction of the blood set in a few minutes after the reinjection of antigen, even though previously treated with various organ extracts (cytozym emulsions). The same change was noted after the injection of anaphylatoxin into guinea pigs. The blood of these animals thus shows the characteristic property previously encountered only in the case of syphilitics.

Vaccine treatment, L. Hektoen (Jour. Amer. Med. Assoc., 66 (1916). No. 21, pp. 1591-1594).—"If the presentations in this paper are trustworthy, it may be concluded that the general results so far from the routine use of commercial vaccines, polyvalent and mixed, have no value as evidence for or against the curative usefulness of vaccine treatment, and hence no value, either, with respect to the soundness of the theory on which vaccine treatment primarily has been developed.

"In subacute and chronic localized infections, the results appear to indicate that specific vaccines properly and skillfully used have value, quite likely because they increase the production of specific antibodies as demanded by the theory, but probably also because they stimulate leucocytic and other activities.

"In typhoid fever, and possibly also in other infectious diseases, the intravenous injection of specific vaccines and also of other substances may induce crisis and prompt recovery. The mechanism of this action is not fully understood; but as it involves something more than or different from specific stimulation of the production of antibodies, it can not be interpreted in terms of the current conception of the action of vaccines. We are entering, therefore, a new and interesting development in the study and treatment of infectious diseases."

The etiology of rat-bite fever, F. G. BLAKE (Jour. Expt. Med., 23 (1916), No. 1, pp. 39-60, pls. 7, ftg. 1).—" Rat-bite fever is a specific infectious disease following the bite of a rat. It occurs in Asia, Europe, and America. The etiological organism is Streptothrix muris ratti, first described by Schottmüller in 1914. His observation is confirmed by the isolation of an identical streptothrix in the case here reported. Invasion of the blood stream by S. muris ratti occurs in rat-bite fever. The case here reported developed a powerful agglutinin for S. muris ratti. Pathological changes occur in the myocardium, kidneys, liver, and adrenals showing areas of degeneration and infiltration with polynuclear leucocytes, lymphocytes, plasma cells, and endothelial cells. Ulcerative endocarditis may occur in rat-bite fever and be caused by the S. muris ratti."

The etiology and treatment of rat-bite fever, W. Tileston (Jour. Amer. Med. Assoc., 66 (1916), No. 14, pp. 995-998, figs. 4).—" In a typical case of rat-bite fever, organisms were feund in the blood, closely resembling the Streptothrix muris ratti of Schottmüller and Blake. They were present in each febrile paroxysm and absent in the intervals. They were readily demonstrated by dark-field illumination, but with difficulty by staining methods, probably on account of a strong tendency to fragmentation. Blood cultures and inoculations of animals with the blood were negative. The administration of salvarsan was followed by immediate cessation of the paroxysms. An abortive case of rat-bite fever is reported."

Chinese animal hides, skins, and bristles, J. R. Shand (Amer. Jour. Vet. Med., 11 (1916), No. 8, pp. 609-615).—This article briefly considers the sanitary conditions to be contended with when hides and skins are imported into the United States from China, and suggests remedies for handling the situation. The methods used for disinfecting the hides and other material in China are briefly discussed.

On the resistance of Bacillus anthracis spores to high temperature, R. H. MALONE and ELEANOR SHANLY (Proc. and Trans. Roy. Soc. Canada, 3. ser., 9 (1915), Sect. IV, pp. 85-88).—The results obtained in the experiments here reported have led the authors to conclude that there is no correlation between any one growth characteristic and the heat resistance of the spores, that strains of B. anthracis and individual spores of the same strain vary in their heat-resisting power, and that there is no specific thermal death point for anthrax spores.

Experiments upon the transmission of rinderpest, A. R. WARD, F. W. Wood, and W. H. BOYNTON (*Philippine Bur. Agr. Bul. 30 (1914)*, pp. 31, pls. 2, figs. 6).—Previously noted from another source (E. S. R., 31, p. 677).

The development of ideas regarding the preparation and use of antirinderpest serum, A. R. Ward (Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 4, pp. 456-470. flgs. 3)—This article discusses the development of the serological treatment of the disease and reports some results obtained in the Philipplne Islands by the use of serum from animals that had merely been immunized in the field, and not hyperimmunized. A bibliography of 24 references to the literature cited is appended.

On the heat resistance of bacterial spores, with a consideration of the nature of the spore-like bodies seen in Bacillus tuberculosis and allied forms, Eleanor Shanly (*Proc. and Trans. Roy. Soc. Canada, 3. ser., 9* (1915), Sect. IV, pp. 121-140, pl. 1, fig. 1).—This paper includes a discussion of the

method employed, cultures made use of, the heat resistance, and the significance of the granules in tubercle and allied bacilli, the thermal death point of the presumed spores of *B. tuberculosis*, etc. It was found that many forms which will survive exposure for 15 minutes at 80° C. are killed by exposure for half an hour, and yet more by exposure for an hour.

On the pathology of bovine actinomycosis, a preliminary report, F. GRIFFITH (Jour. Hyg. [Cambridge], 15 (1916), No. 2, pp. 195-207).—Previously

noted from another source (E. S. R., 34, p. 782).

The Bacillus enteritidis as the cause of infectious diarrhea in calves, K. F. MEYER, J. TRAUM, and C. L. ROADHOUSE (Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 1, pp. 17-35).—The authors' investigations, conducted at the laboratory of the University of California, have led to the conclusion that B. enteritidis is responsible in the United States for certain forms of infectious diarrhea in calves. It is pointed out that our knowledge concerning B. enteritidis and paracolon infections, especially in bovines in this country, is very limited. While the observations do not permit definite conclusions as to the prevention and treatment of infectious diarrhea of calves after the first few days of their lives, they do, however, suggest that when milk of an unknown quality is fed it should first be pasteurized. "Symptomatic treatment is as a rule not satisfactory and not much can be expected from either serum or serum and bacterin treatment unless the specific organism is employed in the production of these biologic products."

Observations of keratitis infectiosa of the reindeer, B. R. Avid (Deut. Tierärztl. Wchnschr., 23 (1915), No. 28, pp. 226-229; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Discases, 6 (1915), No. 9, pp. 1209, 1210).—A summary of investigations of a disease of reindeer found to be identical with keratitis infectiosa of cattle.

Coccidiosis of Egyptian sheep and goats, Mohammed Askar (Agr. Jour. Egypt, 5 (1916), No. 1-2, pp. 50-62, pl. 1).—The discovery of this disease in Cairo abattoirs is recorded and a brief account is given of the causative agent.

Hog cholera: Its control and eradication, O. E. STRODTMAN and W. G. West (Kans. Live-Stock Sanit. Dept., Farmers' Bul. 1 (1916), pp. 16).—This discusses the subject under the heads of causes, symptoms of hog cholera, treatment of infected and exposed herds, methods of using the serum, manner of treatment, and prevention. The symptoms and treatment of lungworms and bowel worms in hogs are also briefly discussed.

Production of clear and sterilized antihog-cholera serum, M. Dorset and R. R. Henley (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 9, pp. 333-338).—For the production of clear and sterilized antihog-cholera serum the authors have devised the following procedure:

Bean extract for agglutinating the blood corpuscles is prepared by soaking 100 gm. of coarsely ground white navy beans for one hour in 500 cc. distilled water, with occasional shaking. The pulp is then strained through cheese cloth or cotton and mixed with powdered kieselguhr and filtered until clear. The clear, filtered extract is then passed through a bacteria-proof filter of infusorial earth.

In preparing the defibrinated blood for centrifugalization 1 cc. of the sterile bean extract is added to each 100 cc. of the cool defibrinated blood. The mixture is allowed to stand until agglutination is clearly evident. One gm. of finely powdered sodium chlorid is added and stirred until dissolved. The mixture of defibrinated blood, bean extract, and salt is allowed to stand for about 15 minutes, placed in suitable containers, and rotated in a centrifuge for 15 minutes at a speed sufficient to produce in the cups a precipitating force equal to approximately 1,700 times gravity. The serum may then be poured from the

cups into suitable containers and sterilized in a container which is surrounded by a jacket of water. The temperature of the water in the outer jacket at the beginning of the heating should not exceed 63° C. The serum in the inner container is slowly stirred during the heating process, care being taken to see that the temperature of the serum does not fall below 60° nor rise materially above it. Continuous heating for 30 minutes at 60° is required. After the sterilization the serum is rapidly cooled, and one part of a 5 per cent solution of phenol added to nine parts of the serum. After the phenol has been added a slight precipitate may at times form in the serum, and it is therefore desirable to allow several days to clapse between the addition of the phenol and the final filtration through infusorial earth.

By the new procedure yields of from 70 to 74 per cent of the perfectly sterilized serum were obtained.

"There seems to be no reason why the process should not be entirely satisfactory for use in the practical production of antihog-cholera serum. There appears to be little or no loss in antibodies; the serum secured is generally clear; and it may be removed from the agglutinated cells easily by pouring from the cups. The method also would seem to tend toward a certain concentration of the antibodies of the blood, and it is also to be recommended on account of the fact that it results in a large yield of serum.

"The fact that this serum may be heated for half an hour at 60° without noticeable impairment of its potency is of much practical importance because there is thus afforded a ready means for safeguarding it against infection with the virus of the foot-and-mouth disease."

Ascariasis in the horse and swine, H. Thum (Ztschr. Tiermed., 18 (1915), No. 11-12, pp. 503-528; abs. in Cornell Vet., 5 (1916), No. 4, pp. 205-209).—A report of observations relating to Ascaris megalocephala in the horse and A. lumbricoides in swine.

Contribution to the study of parasitic affections of the horse.—A clinical study of equine strongylidosis, G. Leneveu (Rev. Gén. Méd. Vét., 24 (1915), No. 288, pp. 593-612; abs. in Jour. Amer. Vet. Med. Assoc., 49 (1916), Nos. 1, pp. 102-106; 2, pp. 161-163).—This is a compilation of information relating to the life history of the nematodes of the genera Strongylus and Cylicostomus that are parasitic in the horse, and to the lesions, symptoms, etc., of which they are the source. These forms occur endemically in various parts of France and especially in Normandy.

The poisonous effects of the rose chafer upon chickens, G. H. Lamson, Jr. (Science, n. ser., 43 (1916), No. 1100, pp. 138, 139).—Substantially noted from another source (E. S. R., 34, p. 655).

RURAL ENGINEERING.

Engineering geology, H. RIES and T. L. WATSON (New York: John Wiley & Sons, 1915, 2. ed., enl., pp. XXVII+722, pls. 104, figs. 249).—This is a second and enlarged edition of this book (E. S. R., 32, p. 784), to which a chapter on historical geology has been added.

Water supply, sewerage, and drainage department [Western Australia], third annual report, year 1914-15 (West. Aust. Water Supply, Sewer., and Drain. Dept. Ann. Rpt., 3 (1914-15), pp. VIII+111, pls. 36).—The activities and expenditures of the department for the year ended June 30, 1915, are reported, including data on irrigation, drainage, and rural water supplies and related hydraulic experimental data.

Water resources of the State of Oregon, J. H. Lewis (Off. State Engin. Oreg. Bul. 4 (1915), pp. 353, figs. 18, pl. 1).—This report, prepared in coopera-

tion with the U. S. Geological Survey, is a summary of the available information relating to the water resources of Oregon.

Report of progress of stream measurements (hydrometric surveys) for the calendar year 1914, F. H. Peters et al. (Dept. Int. Canada, Sess. Paper No. 25c (1915), pp. 508, pls. 20, flgs. 5).—This report contains the results of measurements of flow made on streams and irrigation canals and ditches in Alberta and Saskatchewan during 1914.

Water samples, L. Heimburger (Fla. Quart. Bul. Dept. Agr., 26 (1916), No. 1, pp. 147-152).—This section contains the results of analyses of 25 samples of water from different sources in different parts of Florida.

Status of activated-sludge sewage treatment, G. T. Hammond (Engin. News, 75 (1916), No. 17, pp. 798-801, figs. 10).—From the results observed on inspection of five working scale plants, it is concluded that the activated-sludge process is not as yet out of the early experimental stage and that no forecast as to its value for sewage treatment is now justified. The greatest problem appears to be the economical production of a sludge of such a character as to be of value as a fertilizer base. As an aid in solving this problem the reduction of the volume of sludge-making materials by screening preliminary to activation is recommended.

Reclamation Board Act of the State of California as in effect on and after August 8, 1915 (Sacramento, Cal.: State Reclam. Bd., 1915, pp. IV+41).—The text of the act is given.

Hydraulic and excavation tables, A. P. Davis (U. S. Dept. Int., Reclam. Serv., Hydraulic and Excavation Tables, 1913, pp. 147, figs. 2).—Tables intended for the use of engineers engaged in the design, construction, and operation of irrigation works under the U. S. Reclamation Service are given.

Harper's hydraulic tables for the flow of water in circular pipes under pressure, timber flumes, open channels, and egg-shaped conduits, J. H. Harper (New York: D. Van Nostrand Co., 1916, pp. 192, figs. 39).—This handbook contains formulas and tables for flow of water in circular pipes running full, rectangular channels, open trapezoidal channels, and egg-shaped conduits, together with a large amount of accessory information.

The discharge from vertical pipes, C. E. Grunsky (West. Engin., 7 (1916), No. 4, pp. 182, 183, ftg. 1).—A simple formula for computing the flow of water from vertical pipes, which is especially applicable to computing the discharge

from artesian wells, is given as follows:
$$D = \frac{10d\sqrt{h_o^3}}{\sqrt{1 + 2.525 \left(\frac{h}{d}\right)^2}}$$
. $D = \text{discharge in}$

cubic feet per second, d=inside diameter of the casing in feet, and h_0 =height in feet to which water rises in the center over the top of the casing.

Irrigation module devised for constant flow, J. Barieau (Engin. News, 75 (1916), No. 17, pp. 806, 807, fig. 1).—This device, consisting essentially of a cast-iron base and a number of galvanized sheet-iron cylinders, is described and illustrated in section. It is adjustable and can be designed for any variation in canal level.

Small irrigation canals lined with concrete to prevent seepage water loss, C. E. Edwards (Engin. Rec., 73 (1916), Nos. 16, pp. 508-510, figs. 2; 17, pp. 539-541, fig. 1).—This article gives the details of construction and cost of work on the Okanogan Irrigation Project in Washington. It was found that seepage losses were reduced from 51 to about 15 per cent of the total water received at the headworks.

"Part of the lining has been in use for four seasons and has given good service and shows no signs of wear. Up to date it has required no expense for maintenance, except at a few places on some of the first work where drainage inlets were not constructed at the time the lining was placed. The friction factor for this kind of lining as determined from experiments varies from $n{=}0.01$ for canals having a straight alignment and perfectly free from shifting sand and pebbles on the bottom to $n{=}0.015$ for canals having numerous curves and a limited amount of moving sand along the bottom. No trouble has been experienced on account of expansion or contraction injuring the lining, even when the water is rotated and the canal is dry half the time during the summer."

Comparison of wood and concrete for use in irrigation structures, S. T. Harding (Engin. and Contract., 45 (1916), No. 15, pp. 340-342).—This report deals with the factors involved in a choice between concrete and wood for irrigation structures.

It is concluded "that no general conclusions can be drawn as to the most economical type of construction. For any particular project where the construction costs can be estimated and the other factors, such as financial conditions of the constructing organization, rate of interest, certainty as to type of structure desired, and permanence of its location, can be given proper weight, a decision can be made. Under usual conditions concrete will be the preferable material if the capitalized cost of service alone is considered. The other factors are, however, more usually such as to incline the choice toward wood for first construction, except for the larger and more important structures. That the capitalized cost is being given more consideration and that many systems are reaching a condition where replacements and betterments can be made on a more permanent basis is evidenced by the increasing use of concrete in irrigation structures."

Methods of placing and cost of concrete lining in laterals on Orland Project, A. N. Burch (Reclam. Rec. [U. S.], 7 (1916), No. 4, pp. 178, 179, figs. 3; abs. in Engin. and Contract., 45 (1916), No. 15, p. 352).—Up until February, 1916, there have been lined about 22 miles of laterals on the Orland Project, in sections ranging from a few feet in length and requiring less than a cubic yard of concrete to a maximum section of 8,800 ft. The cross sections of the laterals lined have ranged from a bottom width of 2 ft. and vertical depth of 1 ft. to a bottom width of 8 ft. and vertical depth of 4.5 ft. Laterals originally designed for lining were built with 1:1 bank slopes; other laterals with 1.5:1 and 2:1 slopes. "The aggregates used are run of bank material obtained from creeks in the vicinity of Orland. The proportions of mix are approximately 1:3:5... There is little difference in the cost of lining whether the material be hand or machine mixed, although the machine turns out a better and more uniform grade of concrete."

The total cost per square yard of this work has been 34.3 cts.

Irrigation management, F. H. Newell (New York and London: D. Appleton & Co., 1916, pp. XIII+306, pls. 8).—This is a summary of information on methods of operation, maintenance, and betterment of irrigation works. It contains chapters entitled the problems; the physical conditions; the human element; the legal side; operation organization; methods of operation; records and schedules; water economy; maintenance; expenditures, recording, and classifying; receipts and values; the irrigator and his associations; methods of applying water; the products; and conclusions.

The cost of tile drainage on the Trumbull County experiment farm, H. L. Andrew (Mo. Bul. Ohio Sta., 1 (1916), No. 5, pp. 136-140, figs. 2).—The costs of tile draining 110 acres of land, which included a total of 7,959 rods of ditch, averaging 30 in. in depth, and 123,541 tile in 3, 3½, 4, 5, 6, and 7 in. sizes laid from 33 to 40 ft. apart, are summarized. The cost per acre averaged 8 cts.

for staking, \$21.71 for machine work in cutting trenches, \$17.04 for tile, \$4.15 for hauling tile, \$2.09 for laying tile, and \$1.58 for filling ditches, a total of \$46.65.

Rational method of selecting types evolved for a comprehensive county road system, W. W. Marr (Engin. Rec., 73 (1916), No. 17, pp. 536-538, figs. 4).—It is stated that traffic census, population, and property valuation are the bases used in equalizing the cost for users when designing a county road system in Illinois. Methods of using these factors in the economic selection of road types are described.

Recent developments in the building of concrete roads, W. D. UHLER (Municipal Jour., 40 (1916), No. 14, pp. 481-483, figs. 3).—The conclusions drawn from the construction of a 12-mile model concrete road are given.

It was found that the greatest strength commensurate with economy in cost of mixing was obtained from a mix of $1\frac{1}{2}$ minutes duration.

"Another feature is the great variation in strength of 6-in. cubes of the regular mix, made up daily during the progress of the work and set aside for testing at periods of 7, 14, and 28 days, and 6 months. The 7-day compression test runs from 1,065 to 3.633; the 14-day test, from 1,572 to 4,212; and the 28-day test, from 2,362 to 5,561."

It is concluded that \(\frac{1}{4}\)-in, joints filled with bitumen with edges rounded and protected with bitumen are more satisfactory and economical than steel protected joints. It is further concluded that better results at the same cost may be secured with a 5-in, side and 7-in, center thickness, using light metal fabric reinforcing, than with plain concrete 6 in, thick at the side and 8 in, in the center. It is stated in conclusion "that the essential features for a good concrete pavement are a hard, dense surface, true to grade and cross section, free from waves, depressions, and irregularities, and one which will insure uniform wear."

Various aggregates in test concrete road, W. H. CONNELL (Engin. Rec., 73 (1916), No. 17, pp. 554, 555, figs. 4).—A description of the construction of a two-mile test pavement, made to test some of the latest theories and practice in concrete road construction, is given.

A study of cracks in a concrete roadway at Indiana University, U. S. Hanna (Engin. and Contract., 45 (1916), No. 15, pp. 357, 358, fig. 1).—This is a brief discussion of the cracks in a two-course reinforced concrete road. It is pointed out that "some [of the cracks] are almost certainly due to insufficient lapping of reinforcement. Others appear to be due to failure to secure a subgrade of uniform density. Lack of proper drainage may also have had a part in it."

Concrete road construction in Oakland County, Michigan, M. De Glopper (Municipal Engin., 50 (1916), No. 4, pp. 140-145, figs. 6).—This is an article dealing with the practical details of methods of construction employed on this work.

Second biennial report of the Department of Public Roads made to the governor and general assembly of Kentucky, R. C. Terrell (Bien. Rpt. Dept. Pub. Roads Ky., 2 (1913-1915), pp. 162. pls. 32).—This report covers the work and expenditures, by counties, of the department in Kentucky from November 1, 1913, to November 1, 1915.

Annual report of the Baltimore County [Maryland] roads engineer, W. G. Sucro (Ann. Rpt. Roads Engin. Baltimore Co. [Md.] 1915, pp. 90, pl. 1, figs. 17).—This reports the activities and expenditures of the county roads engineer's office on roads and bridges in the different districts of the county during 1915.

Country roads board [Victoria], first annual report (Ann. Rpt. Country Roads Bd. Victoria, 1 (1914), pp. 94, pls. 7, figs. 88).—This report deals mainly with preliminary work connected with the investigation of highways, the condition of the roads in different districts, and methods of dealing with roads by the Government and municipalities of Victoria.

Recent road legislation of Iowa, edited by H. E. Sampson and T. H. Mac-Donald (Iowa State Highway Com. Serv. Bul., 3 (1915), No. 9, Sup., pp. 104).—The text of the law is given.

The law of Ohio governing roads and bridges, W. M. Rockel (Cincinnati, Ohio: The W. H. Anderson Co., 1916, pp. XL+646).—This gives the text of the Ohio laws governing roads and bridges, including the establishment, construction, improvement, and repair of roads and bridges by state, county, and township officials; and the text of the law as to the adjoining landowners and the traveling public.

Experiments with dynamite, F. Watts (Imp. Dept. Agr. West Indies, Rpt. Bot. Sta. [etc.] Antigua, 1914–15, pp. 29, 30).—Experiments on heavy calcareous loam soil in growing plant and ratoon canes using 2-oz. dynamite cartridges inserted 2.5 ft. deep gave results which are not considered remunerative. In similar experiments on heavy clay soil an increase was obtained in the ratoon crop and a decrease in the plant cane crop.

Gravel as an aggregate for concrete, H. H. Schofield and C. C. Brown (Municipal Engin., 50 (1916), No. 4, pp. 135-137).—A study of existing data on gravel and sand for concrete is reported. The results are taken to indicate "that there is need of an investigation for the purpose of fixing a rational specification for gravel for concrete. Such a specification should take into account, among other things, the durability of the particles, the grading, the cleanness, and the proportions for different classes of natural gravels and for different classes of work."

Amount of water to use in concrete, E. McCullough (Cement Era, 14 (1916), No. 5, pp. 50, 51).—The author reviews his practical experience and reports the results of experiments in which it was found that slightly less than 6 lbs. of water per cubic foot of loose materials produced the ideal mixture for concrete roads. It was also found that a full minute of mixing was necessary to get the water distributed through the mass.

Making mortar impervious and anthracenic oil, R. Feret (Ann. Ponts et Chaussées, 9. ser., 28 (1915), pt. 1, No. 20, pp. 51-71).—Experiments with three Portland cements to determine the influence on the strength and properties of the mortar of the addition of anthracenic oil for waterproofing purposes are reported.

In the first series of experiments a mortar composed of 1 part cement to 3 parts of coarse sand was used, to which the oil was added in amounts of 5 and 10 per cent of the weight of the cement used. It was found that the use of the oil slightly increased the total volume of the mortar without markedly modifying the density. Mortars containing oil were less porous after a week than those without oil. The tensile and compressive strengths of the mortars were considerably decreased, especially when 10 per cent oil was used.

Tests of the permeability under heads of water varying from 20 to 70 meters showed that oil-treated mortar stored 14 days in moist air and 14 days in water was considerably more impervious than the mortar without oil. Mortar stored 14 days in moist air and 38 days in water and containing 5 per cent of oil was more pervious than the mix without oil at heads between 20 and 40 meters, but with higher heads the oil mixtures were less pervious. These results are taken to indicate that it is inadvisable to use more than 5 per cent oil.

In the second series of experiments, the mortar mixtures used were 600 kg. of cement per cubic meter of fine sand, 500 kg. of cement per cubic meter of coarse sand, and 400 kg. of cement per cubic meter of gravelly sand containing a large amount of grains of a diameter varying between 5 and 20 mm. The proportions of oil used were 3 and 5 per cent of the weight of the cement. It was found that, with the exception of some of the tests on the fine sand mortar, the mortar containing 3 per cent of oil was less pervious than that without oil. When 5 per cent of oil was used the results in this respect were very variable. At the higher heads these mortars were more pervious than the mortar containing 3 per cent of oil. The addition of 3 per cent of oil did not appreciably decrease the strength of the mortar or its power of adhering to iron. The results as a whole are taken to indicate that 3 per cent of oil may be used to advantage in cement mortar.

See also a previous note by the author (E. S. R., 30, p. 889).

The influence of compression in internal-combustion engines, R. E. Mathot (*Power*, 43 (1916), No. 15, pp. 512-514, figs. 2).—It is shown that within certain limits neither the amount of compression nor the heat value of the fuel affects the output of the engine, although the former does affect the economy.

Tables of data from actual practice covering over 600 tests on about 40 different makes of internal-combustion engines are also included, showing the proper mixtures and compressions to be used with different fuels in order to attain the best results.

Some engine plow troubles and their remedies, C. O. Reed (Amer. Thresherman, 18 (1916), Nos. 11, pp. 68, 69; 12, pp. 14, 15, figs. 3).—Information regarding the prevention of excessive draft, failure to scour, uneven furrow crowns, and failure to penetrate is given, together with brief instructions regarding laying out fields and buying and starting a new plow.

Recent inventions in machines for tilling the soil, M. Castelli (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 11, pp. 1424-1437).—This article describes some of the more recent improvements in tillage machinery, dealing mainly with mechanically propelled types.

Mechanical cultivating apparatus, M. RINGELMANN (Rev. Vit., 43 (1915), Nos. 1112, pp. 305-310; 1115, pp. 361-366; 1116, pp. 377-383).—A number of types of mechanically operated tillage machines for use in truck and vineyard work are described.

Culture machinery, G. Coupan (Encyclopédie Agricole. Machines de Culture. Paris: J. B. Baillière & Sons, 1915, 2. ed., pp. XIV+480, figs. 376).—This is a number of the Encyclopédie Agricole and deals in general with the machines and mechanical methods employed in the preparation of the soil, the spreading of fertilizers and seeds, and the maintenance of culture. A large amount of mechanical, mathematical, diagrammatical, and practical data related to the construction and operation of the different machines is given.

Experiments on the draft of a model plow under different working conditions and their practical application, G. Kühne (Untersuchungen über den Zugwiderstand eines Pflugwerkzeugmodelles bei verschiedenen Arbeitsbedingungen und ihre Anwendung auf praktische Verhältnisse. Inaug. Diss., Univ. Giessen, 1914, pp. 49, flgs. 24).—The factors affecting the draft of a moldboard plow are discussed, experimental apparatus is described, and laboratory experiments with a model moldboard plow are reported to determine the influence on draft of different physical factors under different working conditions in soils artificially prepared.

It was found in sand and loam soil that by steadily increasing the speed of plowing under the same working conditions the plowing draft steadily in-

creased to a certain limit and then decreased with increasing speed. By steadily increasing the working depth in sand and loam soil under the same working conditions the draft increased in approximate proportion to the depth until an optimum draft with reference to cross section was reached, and thereafter increased faster than the depth. Steadily increasing the width of plowing produced results in draft similar to those produced by varying the depth of plowing only in sand soil.

The soils were artificially compressed. The plowing draft increased with increasing compactness of a uniformly damp sand soil at a rate greater than a proportional rate. The draft also increased with the increasing dampness of a sand soil up to a certain limit and thereafter decreased. In a soil dampened irregularly the draft increased with decreasing dampness. The practical application of these methods and results to field conditions is also discussed.

Comparison of team and tractor for hauling gravel, O. L. Kipp (Municipal Engin., 50 (1916), No. 4, pp. 138, 139).—Data are presented from the gravel checker's records on five team-hauling jobs totaling 22 miles of road gravelled and 1 tractor-hauling job covering 3.6 miles of road gravelled, the gravel being placed at the rate of 15 cu. yds. per 100-ft. station on each job. A 36-60 horse-power caterpillar gas tractor and a train of 3.5-yd. reversible spreader wagons with a 50-yd. storage bin and a belt conveyor loader were used.

"It would appear that the cost of hauling by tractor was considerably less than by teams. The advantage in favor of the tractor would have been greater had there been more power available. A 40-80 tractor would have made a much better showing. Another factor cutting down the capacity of the train was the inability of the loading equipment to supply gravel fast enough... It would appear that efficiency in team hauling and consequent low cost is largely dependent upon, and might easily be secured by, obtaining the maximum efficiency in loading." Features in favor of tractor hauling were that, first, by applying the gravel in two courses with a tractor the gravel is rolled without additional cost and the road is ready for travel as soon as the gravel is applied, instead of a month or more later, as with teams; and second, by loading into a bin, thence to wagons, and thence to the road, an efficient mix of the materials is obtained.

Knots and splices, I. D. CHARLTON (Wash. Agr., 9 (1916), No. 7, pp. 191-195, figs. 4).—A few of the more simple and common knots used in farm work with rope are described and illustrated.

Barns for Wisconsin dairy farms, F. M. White and C. I. Griffith (Wisconsin Sta. Bul. 266 (1916), pp. 32, figs. 25).—This bulletin discusses the general requirements of and the more important factors to be considered in the construction of barns for dairy farms to meet Wisconsin conditions and describes three general-purpose barns, one single story dairy barn, and a pioneer barn. Rectangular barns are considered more satisfactory than round ones, and gambrel roofs are preferred to gable roofs.

Construction of fresh air brooders, H. E. UPTON (Brit. Columbia Dept. Agr., Live-Stock Branch, Circ. 3, 2. ed. (1913), pp. 6, figs. 6).—This structure is briefly described and illustrated.

Winter storage of potatoes, E. Schaffnit (Ztschr. Landw. Kammer Braunschweig, 84 (1915), No. 28, pp. 245-249, figs. 2).—In outlining the conditions for proper winter storage of potatoes, it is pointed out that the potatoes must be absolutely protected from frost, and must, at the same time, be kept dry and not too warm, as both heat and dampness are favorable to the rotting of potatoes.

Water problem simplified, W. A. ETHEBTON (Farm Engin., 3 (1916), No. 11, pp. 249, 250, figs. 4).—A simple water supply system consisting essentially of a pump, hot-water tank, and sink, and employing a three-way cock for supplying hot and cold water, is described and illustrated.

RURAL ECONOMICS.

What is agricultural economics? E. G. Nourse (Jour. Polit. Econ., 24 (1916), No. 4, pp. 363-381).—The author points out that agricultural economics is an application of general economics to the practical business of agriculture rather than an independent study of doctrines built up out of a specialized body of data.

"An examination of text-books and college announcements seems to indicate that at present most courses with a rather detailed study of production (now often including marketing) and, except for the many who stop with that, leap over to a fragmentary discussion of distribution as touching the farmer's profits. But this is no adequate preparation for meeting the more intricate problems facing modern agriculture. The student, besides examining the economic factors in technical productive efficiency, needs to understand the laws of value and the process by which physical units of product are fitted to psychic units of want through the agency of an exchange mechanism; he needs to consider not only how this aggregate lump of values is broken up into private incomes, but how the use of this wealth in private hands reacts upon the further operation of the system. Even when for practical reasons the course in agricultural economics must be much compacted, it should be reduced to a stout framework of fundamental principles instead of bloating into a flabby mass of descriptive generalities. . . .

"Our purpose in elaborating an economics of agriculture is to train the agriculturist in the business principles which govern the commercial success or failure of his enterprise, but not less to enable him and likewise those others who are not engaged in agriculture to perceive the economic results which will flow from one sort of agricultural organization or another, from one sort or another of consumption of our resources of land, labor, and capital."

Economic cycles: Their law and cause, H. L. Moore (New York: The Macmillan Co., 1914, pp. VIII+149, figs. 27).—The author attempts to trace the influence of the weather upon crop production and the influence of variations in crop production upon prices. He claims that the fundamental, persistent cause of the cycles in the yields of the crops is the cyclical movement in the weather conditions represented by the rhythmically changing amount of rainfall. These cycles are of 33 and of 8-year periods.

The falling yield in crops leads to a diminution of the volume of trade, a decline in the demand for producers' goods, a fall in the prices of producers' goods, a decrease in employment, and a fall of the demand curves for crops, with the final result of a fall in general prices. Similarly, a rising yield in the crops leads to an increase in the volume of trade, an increase in the demand for producers' goods, an increase of employment, and a rise in the demand curves for crops, with the final result of a rise in general prices.

He states that the cycles in the yield per acre of crops are followed at an interval of two years by cycles in the activities of industry and in the volume of trade, and at an interval of about four years by cycles in prices.

Wages and rural migration, A. Beckerich (Ann. Sci. Agron., 4. ser., 4 (1915), July-Sept., pp. 85-214).—The author discusses the movement of wages of the different classes of agricultural workers in various agricultural regions of France, the movement of prices of agricultural products and the number of

agricultural workers, and the influence of agricultural machinery and the introduction of foreign laborers. A brief bibliography is appended.

Results of a survey of state marketing activities throughout the United States (U. S. Dept. Agr., Office Markets and Rural Organ. Doc. 3 (1916), pp. 7).—This is a summary by States, based on the replies to a questionnaire sent to representative officials in each State to determine what States have established official marketing departments, the agency charged with this work, and the nature and scope of the work being done, both by such specially created departments and by the extension divisions of the State agricultural colleges.

Associations for marketing meat in Germany, H. Horst (Landw. Jahrb., 48 (1915), No. 1, pp. 1-136, fig. 1).—This article points out the causes of the formation of associations to slaughter live stock and market their products, and gives the aims and organization of the associations and their development in different regions of Germany.

The Grange in Canada, H. MICHELL (Bul. Depts. Hist. and Polit. and Econ. Sci., Queen's Univ. Ontario, No. 13 (1914), pp. 20).—This report contains a brief historical sketch of the Grange movement in Canada.

Ohio agricultural statistics, 1914–15 (Ohio Agr. Statis., 1914–15, pp. 78).—This report gives statistical data gathered by the township assessors concerning the acreage and production of the principal agricultural crops, the number of live stock, quantity of live-stock products, and other facts relative to the agriculture of Ohio.

[Trade and commerce in agricultural products in Chicago], 1915 (Ann. Rpt. Bd. Trade Chicago, 58 (1915), pp. XXXIX+142).—This volume contains the reports of the different committees of the Chicago Board of Trade and the daily and monthly movement during 1915 of the principal agricultural products by routes, prices, and freight rates, together with the acreage, production, and value of live stock and crops in the United States and in the different countries of the world. An appendix is given showing the rules, by-laws, and regulations of the board.

Prices and supplies of grain, live stock, and other agricultural produce in Scotland (Agr. Statis. Scotland, 3 (1914), pt. 3, pp. 183-237, figs. 2).—This report continues data previously noted (E. S. R., 33, p. 492).

Agricultural and live stock statistics of Finland (Statis. Arsbok Finland, n. ser., 11 (1913), pp. 109-127; 12 (1914), pp. 116-143).—This continues data previously noted (E. S. R., 30, p. 692).

Price statistics (Unyar. Statis. Mitt., n. ser., 44 (1913), pp. IX+62*+427).—This volume contains statistical data showing prices and index numbers for agricultural and other products in Hungary for a long series of years.

Supply of foodstuffs and prices in foreign countries during the war (Ztschr. Agrarpolitik, 14 (1916), No. 1, pp. [1-8]).—This article gives the quantity of the principal agricultural crops available in the countries at war with Germany, together with prices. Similar data for previous years are also given for comparative purposes.

World's production of foodstuffs and raw materials, and the provisions from German Colonies in the past and possibilities of the future, A. Schulte IM Hofe (Tropenpflanzer, Beihefte, 16 (1916), No. 1-2, pp. V+177).—In this report are discussed the world's production and trade in various agricultural and live-stock products and fertilizing materials, and the influence of the colonial possessions of different nations in contributing foodstuffs to the mother country. The discussion is accompanied by a large number of statistical tables.

Statistics of commerce of the French Colonies, 1913 (Statis. Com. Colon. Franc., 1913, I, pp. 1197; II, pp. 1069).—In this report are given statistics

concerning the trade in agricultural and other products, showing sources and destination.

Review of the trade of India, 1914-15 (Dept. Statis. India, Rev. Trade India, 1914-15, pp. II+139+VII, pts. 7, figs. 5).—This report gives a review of the effects of the war on the foreign and inland trade of India, as well as statistical data showing the imports and exports by articles, wholesale prices, wages paid in selected industries, customs revenue, number and tonnage of vessels engaged in foreign and coastwise trade, and freight rates. Comparative data are given for earlier years.

AGRICULTURAL EDUCATION.

Graduate work in horticulture, M. J. Dorsey (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 70-77).—The relation between the present status of horticulture and graduate work or advanced training which will so intimately influence future development is discussed, including a consideration of the preliminary training for graduate work, the laboratory method, the relation between graduate work and station research, and factors influencing graduate work. The author concludes that "emphasis must be placed again and again upon fundamental training, as well as upon a knowledge of the material. Science, truth, and proof are just the same in the applied fields as in the pure sciences, and this should be made clear to every graduate student. When full recognition is given to this, research will mean just as much scientifically in the applied fields as in the pure sciences, and the weakness of one-sided practical training will become more and more apparent."

Required trips for horticultural students, F. N. Fagan (*Proc. Soc. Hort. Sci., 11 (1914), pp. 37–40*).—The author gives an account of a horticultural inspection trip taken with 24 students in the summer of 1914, visiting fruit and seed farms, vegetable forcing and trucking, flower growing, and spray machinery places, nurseries, parks, canning and evaporation houses, greenhouse firms, basket and barrel factories, and cold storages, in western New York and northern and northwestern Pennsylvania. This was accomplished in about 28 or 30 working days, at an average expense of from \$80 to \$130 a man.

These trips have been required of junior horticultural students at the Pennsylvania College since the summer of 1913. To receive the six credits allowed for this summer work the students must submit during the first half of their senior year a typewritten report of the trip. Prior to 1913 junior horticultural students were required to spend at least six weeks working on commercial horticultural farms. It was found, however, in many cases that the students often were not engaged in true horticultural work on these farms and were given one job practically the entire summer. Hence the inspection trips were substituted for this work.

One phase of agricultural education in Indiana: Supervision of home project work, Z. M. SMITH (Dept. Pub. Instr. [Ind.], Ed. Pubs., Bul. 22 (1916), pp. 28, figs. 26).—This bulletin reports on (1) the supervision by 21 teachers of home-project work in Indiana in 1915, comprising the work of 7 vocational agricultural teachers, employed by as many townships as supervisors of summer projects of 136 men and boys, and the work of 14 teachers employed jointly by the local authorities and the Purdue University extension department in supervising the projects of 420 boys and girls; (2) home problems reached; (3) the supervision of club project work by county agricultural agents who organized 112 clubs with a total membership of 3,697 boys and girls; (4) the short-course week at Purdue University in January, 1916, which

was the culmination of the 1915 home-project work; and (5) records of a few club members.

The Indiana State Board of Education has decided that school authorities be authorized to give credit for summer home-project work (club work) on condition that a competent teacher be employed to give close supervision over the work, that the quality or grade of work done and the time actually spent on the project by the pupil be considered on the same basis as regular school work, and that each pupil keep detailed records of time and other items of cost and income and submit to the school authorities a full and complete report of his work, subject to the inspection of the state department.

Home education, ELLEN C. LOMBARD (*Rpt. Comr. Ed.* [*U. S.*], 1915, *I*, *pp. 361–369*).—A review is given of the problems of the field of home education in this country and its insular territories, and of the work of the different Government agencies, the National Congress of Mothers, parent-teacher associations, and the General Federation of Women's Clubs for the promotion of home education outside of the school.

The principles of plant culture, E. S. Goff (New York: The Macmillan Co., 1916, 8. ed., pp. XXIII+295, figs. 177).—This text, which is intended for beginners in agriculture and horticulture and especially for students who have had little or no previous instruction in botany, was first published by the author in 1897 (E. S. R., 8, p. 793) and has since undergone several revisions, the present revision being by J. G. Moore and L. R. Jones. It is a systematic study of plant culture which grew out of the author's experience in the lecture room and laboratory while giving instruction to students in the short course in agriculture in the University of Wisconsin. A syllabus of laboratory work is appended and the preface includes a biographical sketch of the author, who died in 1902.

Courses in systematic vegetable gardening, P. Work (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 33-37).—The vegetable gardening courses offered at Cornell University are described.

Report of the committee on floricultural courses, A. C. Beal (*Proc. Soc. Hort. Sci.*, 11 (1914), pp. 40-43).—The author gives historical data on floricultural teaching, the first floricultural courses, extending through four years, having been offered in the School of Horticulture of the Illinois Industrial University in 1875-76.

MISCELLANEOUS.

Monthly Bulletin of the Ohio Experiment Station (Mo. Bul. Ohio Sta., 1 (1916), No. 5, pp. 129-160, figs. 8).—This contains several articles abstracted elsewhere in this issue; Wool Studies, by J. W. Hammond, an abridgment of Bulletin 294 (see p. 477); Heavy Silage v. Heavy Grain, Feeding for Dairy Cows, by C. C. Hayden, an abridgment of Bulletin 155 (E. S. R., 16, p. 811); Controlling the Grape-berry Worm, by W. H. Goodwin, an abridgment of Bulletin 293 (E. S. R., 35, p. 358); and the following special articles: Fruit-bud Formation on Apple Trees, by A. D. Selby, and Shall We Fertilize Corn in the Hill, by C. E. Thorne.

Monthly Bulletin of the Western Washington Substation (Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1916), No. 3, pp. 16, figs. 3).—This number contains brief articles on the following subjects: Notes on Bee Management, by J. W. Ware; Rose Pests and Their Control, by J. L. Stahl; Summer Cultivation, by E. B. Stookey; Milk-fed Chickens, by G. R. Shoup; A Penny Saved is a Penny Earned, by Mrs. G. R. Shoup; and Experiment Station Dairy Barn, a description of the dairy stable and shed at the substation.

NOTES.

Iowa College.—According to a note in *Minnesota Farm Review*, Kenneth McGregor, instructor in animal husbandry, has been appointed in charge of the department of animal husbandry in the University of Alberta.

Maryland College and Station.—Recent appointments include C. J. Pierson as assistant in the department of entomology and zoology in the college, O. I. Snapp as fellow in insect investigations in the college and station, and Dr. Philip Garman as assistant entomologist in the station.

Michigan College.—Science states that G. R. Johnstone has resigned as instructor in botany to take up graduate work and has been succeeded by H. E. Young of the Missouri Botanical Garden.

Virginia College and Station.—During the summer, field meetings have been held at several of the county substations, affording opportunities to many farmers to observe the results of the fertilizer experiments, crop rotations, cultural treatments, variety studies, etc. The substations are regarded as rendering valuable service to the farmers in the solution of local problems.

J. Thompson Brown, J. B. Watkins, and J. A. Turner have been reappointed to the board of trustees. W. B. Ellett has been assigned a teaching course in agricultural chemistry in the college in addition to his duties as station chemist. H. E. Thomas, a 1916 graduate of the college, has been appointed assistant plant pathologist, while K. E. Quantz has been transferred from the department of plant pathology to that of horticulture. J. T. Grissom resigned August 1 as assistant chemist to engage in commercial work. A. A. Ingham, instructor in horticulture, has also been appointed assistant horticulturist in the station.

Virginia Truck Station.—H. H. Zimmerley has resigned as assistant horticulturist to accept a position as demonstration agent for Kent County, Delaware.

West Virginia University and Station .- Among the changes effective July 1 was the resignation of I. S. Cook as professor of agronomy and agronomist. Professor Cook has been appointed county agricultural agent of Ohio County, with headquarters at Wheeling, vice Horace Atwood resigned to become poultryman in the station, and has been succeeded by Forest W. Stemple. O. M. Johnson resigned as professor of farm management to become state agent for the Ohio State University. Charles E. Stockdale was appointed editor of the station and extension department. E. A. Tuckwiller resigned as assistant animal husbandman in charge of beef cattle at Lewisburg to become extension specialist in animal husbandry at the station, and was succeeded by R. H. Tuckwiller. R. R. Jeffries resigned as extension specialist in horticulture to become county agent at Cañon Falls, Colo., and was succeeded by W. R. Legge. George W. Burke was appointed assistant chemist in the station, Robert B. Dustman extension specialist in agronomy, and S. A. Cody specialist in poultry husbandry extension work. David H. Kauffman resigned from the extension work in soils.

F. E. Bear has resigned as soils chemist and head of the soils department, effective September 15, to become professor of soils at the Ohio State University.

# RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Organic agricultural chemistry, J. S. Chamberlain (New York: The Macmillan Co., 1916, pp. XVII+319).—This volume is divided into three sections: (1) Systematic, which includes the study of the composition, constitution, character, and relationship of the more important organic compounds occurring in plants and animals; (2) physiological, which embraces a study of the chemical reactions involved in the fundamental processes of living organisms, in the utilization of food by animals, and in photosynthesis in plants; and (3) crops, foods, and feeding, which includes the study of the distribution of food constituents in agricultural crops and the principles of animal foods and feeding. The presentation of the subject matter is general and of such a nature as to follow a course in general chemistry.

An introduction to the physics and chemistry of colloids, E. HATSCHEK (*Philadelphia: P. Blakiston's Son & Co., 1916, 2. ed., pp. IX+107, figs. 17*).— This is the second edition of a volume, the subject matter of which has been essentially noted (E. S. R., 29, p. 608). The only substantial addition to the text of the first edition is an appendix on experimental technique.

Studies on plant colloids, II-VI, M. SAMEC ET AL. (Kolloidchem. Beihefte, 4 (1912), No. 3-5, pp. 132-174, figs. 13; 5 (1913), No. 5, pp. 141-210, figs. 31; 6 (1914), No. 1, pp. 23-54, figs. 12; 7 (1915), No. 6-12, pp. 137-171, figs. 9; 8 (1916), No. 1-2, pp. 33-62, figs. 7).—Five papers are presented.

II. The stability of starch solutions, M. Samec.—Continuing the study previously noted (E. S. R., 30, p. 111) it is shown that the viscosity of a starch solution decreases appreciably with time. The final viscosity of a 1 per cent starch solution lies within the limits of the viscosity of molecular disperse systems. This decrease in viscosity is greater in dilute than in concentrated solutions. Hydrochloric acid retards the initial viscosity of starch solutions, but later prevents a decrease (stabilizer). Alkalis in the lowest concentration increase the viscosity of starch solutions and in higher concentrations coagulate them. Of the neutral salts ammonium sulphate and ammonium thiocyanate also decrease the internal molecular friction of the starch particles. The sensitiveness to the action of electrolytes decreases with increasing age of the starch solution. With a decrease of internal friction the electrical conductivity increases.

The removal of the ash, the action of electrolytes, and also the change in the behavior of starch in the electrical field can be explained as due to the presence of an ionized starch-phosphoric-acid complex.

III. Changes in starch by removal of the ash and solution, M. Samec and F. von Hoefft.—The three processes of removing the ash, solution, and aging produce the same changes in the properties of starch, viz, a decrease in the internal friction and in the influence of acids and bases on the latter. The rapidity of the changes is proportional to the temperature. Simultaneously with a decrease in viscosity there is an increase in the electrical conductivity and a decrease in the amount of starch precipitable by alcohol. The osmotic pressure is only slightly lowered, while the optical rotation is slightly increased. The titratable acid is also increased. At ordinary temperatures only small amounts of electrolyte can be extracted from the starch by water, but as the starch grains swell the amount extracted increases. It is indicated that the above observations and many others made by earlier investigators can be explained by the presence of an amylophosphoric acid.

IV. The displacement of the phosphoric acid content by a change of condition of the starch and by diastatic cleavage, M. Samec.—From starch grains which had been treated with potassium hydroxid a fraction containing phosphorus and a phosphorus-free fraction were isolated. By the diastatic cleavage phosphorus-containing dextrins which possessed all the properties of electro-negative colloids were obtained. On boiling with water these dextrins were destroyed and phosphoric acid was set free.

V. On soluble starch, M. Samec and S. Jencic.—Starch, in being converted to the soluble form, was essentially changed in structure. In most instances a contraction of the starch particles was apparent, while in exceptional cases there was no alteration. Most soluble starches contain phosphorus, but not those prepared according to the procedure of Malfitano and Moschkoff a and those prepared by heating in glycerin. On account of the variations in the physicochemical characteristics of the so-called soluble starch the term is considered scientifically inadequate. The experimental procedures used in the investigation are described in detail.

VI. On alkali starch, M. Samec.—By the action of alkalis on starch a number of different modifications could be demonstrated. The formation of two of these was attributed to the action of the alkali with the phosphoric acid of the starch (amylophosphate). By the continued action of the alkalis they are also bound at other points in the starch molecule, forming amylates. These substances finally cause a cleavage of the starch complex.

Crystalline  $\beta$ -methyl fructosid and its tetracetate, C. S. Hudson and D. H. Brauns (Jour. Amer. Chem. Soc., 38 (1916), No. 6, pp. 1216-1223).

A fourth crystalline pentacetate of galactose and some related compounds, C. S. Hudson and J. M. Johnson (*Jour. Amer. Chem. Soc.*, 38 (1916), No. 6, pp. 1223-1228).

The determination of phosphoric acid by the uranylacetate method, D. Crispo and R. W. Tuinzing (Verslag. Landbouwk. Ondersoek. Rijkslandbouwproefstat. [Netherlands], No. 17 (1915), pp. 142-156; Landw. Vers. Stat., 88 (1916), No. 1-2, pp. 131-141).—A modified procedure for the uranyl-acetate method for the determination of phosphoric acid is described in detail. The phosphoric acid is first precipitated as ammonium-magnesium phosphate, the precipitate dissolved in acetic acid, and the solution then titrated with the standard uranium solution. The method is applicable to the determination of the various forms of phosphoric acid present in fertilizers without the usual inherent difficulties. Experimental data submitted, comparing the proposed procedure with the official methods of Lorenz and Pemberton, indi-

^a Compt. Rend. Acad. Sci. [Paris], 150 (1910), No. 11, pp. 710, 711; 151 (1910), No. 19, pp. 817-819.

cate its accuracy. The uranyl oxid can be easily recovered from the phosphate precipitate.

On the solubility of phosphoric acid in Thomas slag by extraction with water containing carbon dioxid, J. G. Maschhaupt (Verslag. Landbouwk-Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 17 (1915), pp. 97-141, figs. 5).—Analytical data indicating the amount of phosphoric acid of Thomas slag soluble in water containing carbon dioxid, with various amounts of calcium oxid and silicate present in the slag, are submitted in detail. The data are discussed and the value of such a procedure for determining the available phosphoric acid in slag fertilizers is emphasized.

Experiments on the extraction of potash from wyomingite, R. C. Wells (U. S. Geol. Survey, Prof. Paper No. 98-D (1916), pp. 37-40).—This paper records experimental data on the chemical and mineral composition of wyomingite (a lava occurring extensively in the Leucite Hills in Sweetwater County, Wyo.), its behavior in water, and the effect of heating with gypsum, sulphuric acid, potassium bisulphate, alunite, calcium carbonate, calcium chlorid, magnesium chlorid, a bittern, and ammonium sulphate. The percentage of the total potash extracted by heating with the various materials ranged from 16.2 to 57, the largest amount being obtained by heating with alunite.

It is indicated that while the experiments described can not all be considered as commercial possibilities they may be suggestive to other investigators and save the repetition of considerable preliminary investigation.

A new apparatus for the determination of soil carbonates and new methods for the determination of soil acidity, E. Truog (Jour. Indus. and Engin. Chem., 8 (1916), No. 4, pp. 341-345, figs. 2).—A new form of apparatus, using the absorption tower previously noted (E. S. R., 34, p. 504), and its manipulation are described in detail.

Experimental evidence indicates that there exist in the soil two kinds of acidity which are designated as active and latent. Methods for their separate determination are proposed. It is further indicated that "soil acidity is due to true acids and not selective ion adsorption by colloids; the avidity of the active acids in different soils varies greatly, which is of prime importance." See also a previous note by the author (E. S. R., 34, p. 419).

The analysis of Hawaiian soils, W. T. McGeorge (Hawaii Sta. Rpt. 1915, pp. 33-36).—Slight modifications in the official methods to meet certain peculiarities encountered in Hawaiian soils, notably the high content of iron, aluminum, titanium, and manganese, are presented, together with results secured with four soils as to the influence of the time of digestion upon the solvent properties of hydrochloric acid.

On the determination of small quantities of hydrocyanic acid, M. O. Johnson (Jour. Amer. Chem. Soc., 38 (1916), No. 6, pp. 1230-1235, fig. 1).—The method described by Francis and Connell (E. S. R., 30, p. 709) has been shown to require certain modifications, which the author has embodied in a convenient and accurate procedure for the determination of small quantities of hydrocyanic acid. The potassium thiocyanate is extracted with acetone and then determined colorimetrically by the production of the ferric thiocyanate. Any organic coloring matter which may interfere with the color of the ferric thiocyanate is removed from the solution by extraction with ethyl acetate.

The procedure was evolved in connection with some chemical work on cassava at the Hawaii Experiment Station.

The microscopy of vegetable foods, A. L. WINTON, J. MOELLER, and KATE B. WINTON (New York: John Wiley & Sons, Inc., 1916, 2. ed., rev. and enl., pp. XIV+701, figs. 635).—This volume is the second edition of the work previously noted (E. S. R., 17, p. 1096) and deals with the microscopy of vegetable foods,

with special reference to the detection of adulterants and the diagnosis of mixtures. The first part is devoted to general considerations, methods, apparatus, reagents, etc., while the succeeding parts are devoted to the microscopy of the individual substances. The subjects considered are cereal products, together with the commonly associated impurities; oil seeds; legumes; nuts; fruit and fruit products; vegetables, such as tubers, roots, fungi, etc.; alkaloidal products and their substitutes; spices and condiments; and commercial starches. The text is fully illustrated and a general bibliography and glossary are included.

Quantitative sublimation and its application in food analysis, Madame Gobert (Ann. Falsif., 9 (1916), No. 88-89, pp. 96-98, fig. 1).—This article describes a small sublimator which is easily constructed and yields quantitative results. A method for the determination of caffein in coffee and in tea, using this apparatus, is also described.

Studies on commercial chicory, M. Sibot and G. Joret (Ann. Falsif., 9 (1916), No. 88-89, pp. 48-63).—This article describes commercial chicory products and indicates the regulations adopted by the Congress of Paris in 1909 for the control of the purity of the material. Complete analytical data of a number of genuine samples, together with data of adulterated samples and imitations, are submitted in detail and briefly discussed.

The determination of the constituents of cotton seed and peanuts and their determination in feeding stuffs, J. A. EZENDAM (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 17 (1915), pp. 89-96, pl. 1).—The author describes a microchemical method for the determination of the presence of cotton-seed meal in a mixed feeding stuff and also a procedure for the determination of small amounts of peanut oil cake.

The action of copper solutions on sucrose. Determination of invert sugar in the presence of sucrose, E. Saillard (Compt. Rend. Acad. Sci [Paris], 161 (1915), No. 20, pp. 591-593).—In determining reducing sugars in the presence of sucrose an error is introduced which yields high results. The increased reduction is dependent on the concentration of the sucrose and of the reducing sugars, on the copper solution, and on the manner of heating. Analytical data submitted demonstrate that an increase in the quantity of invert sugar present decreases the amount of reduction of sucrose. When the reducing sugars correspond very nearly to the amount of copper in solution the reduction is practically negligible. The time of heating and the concentration of the solution also affect the amount of reduction of sucrose. The following procedure for the determination of reducing sugars in beets, sirups, sugars, and molasses is proposed:

A normal solution of the material is cleared with lead subacetate, the excess lead removed with sodium carbonate, and the reducing sugars determined in 50 cc. of the clear filtrate by adding 10 cc. of copper solution and 10 cc. of alkaline solution and heating for 22 minutes on the water bath at from 62 to 64° C. The cuprous oxid is then filtered on an Allihn tube and determined according to the Bertrand procedure. The alkaline solution used in the modified procedure is less concentrated than the one generally recommended.

The determination of sucrose in beet molasses (Clerget-Saillard double neutral polarization method), E. Saillard (Rev. Gén. Chim., 18 (1915), No. 2, pp. 42-46).—As previously noted (E. S. R., 28, p. 711), the author maintains that the presence of nitrogenous substances (asparagin, aspartic acid. glutamin, glutamic acid, etc.) so influences the plane of rotation as to make the method of Clerget unreliable. A modified procedure which obviates the effect of the nitrogenous substances present by determining the polarization in a neutral solution is described in detail. The effect of various salts on the

sucrose, the invert sugar, and on the nitrogenous substances in the sugar solution was also studied and the results recorded. Analytical data indicate the accuracy of the modified method by the close agreement with results obtained by the usual copper-solution procedure.

A new species of alcohol-forming bacterium isolated from the interior of stalks of sugar cane infested with the cane borer Diatræa saccharalis, W. L. Owen (Jour. Bact., 1 (1916), No. 2, pp. 235-246, pl. 1).—The morphological, cultural, and physiological characteristics of a new species of alcohol-forming bacterium isolated from borer-infested sugar cane, which the author has named Bacillus saccharalis, are described in detail. Sucrose, glucose, levulose, mannite, lactose, galactose, raffinose, maltose, and glycerin are all fermented by the organism. From field experiments on the sugar cane it is concluded that "B. saccharalis does not induce any marked deterioration of the juice of growing cane, and indeed the apparently negative results which indicated a higher purity in the inoculated canes is well within the range of possible results from the action of the species."

The conservation of potatoes by spontaneous and pure culture inoculation souring, W. VÖLTZ and H. JANTZON (Landw. Jahrb., 48 (1915), No. 4, pp. 493-534).—Two methods for conserving the surplus potato crop, later to be used as stock food, are described in detail.

It has been demonstrated that for raw potatoes only water-tight pits (concrete or mortar lined) are practicable. Under average favorable conditions the total loss of nutrients is never more than from 5 to 10 per cent. In using earth pits for steamed potatoes the loss in nutrients is never more than from 15 to 20 per cent. With water-tight pits this is reduced to from 5 to 10 per cent.

The spontaneous souring process is not recommended for general use on account of the possibility of infection by pathogenic micro-organisms, which would yield a spoiled product unsafe for use as a feed. The pure culture method, using steamed potatoes which are inoculated with *Bacillus cucumeris fermentati*, *B. lactis acidi*, *B. delbrücki*, or mixed cultures of lactic acid bacteria, is easy and practical and yields the most reliable results.

No difficulty was experienced in feeding the product to animals, preliminary data indicating it to be of great value for milch cows.

Analytical data showing the composition of the potatoes before and at various stages in the souring are also submitted.

Report to the Michigan legislature on the feasibility of using the pulp and chicory dryers in the State to dry the surplus potato crop, A. C. Carton (Lansing, Mich.: Pub. Domain Com., 1915, pp. 43).—This pamphlet reports the findings of the secretary of the Public Domain Commission in his investigation to ascertain the commercial possibilities of dried potatoes or potato flour in the domestic and foreign market, and as to the utilization of the pulp driers in the large sugar and chicory factories.

### METEOROLOGY.

The value of high-level meteorological data in forecasting changes of temperature: A contribution to the meteorology of Mount Rose, Nevada, S. P. Fergusson (Nevada Sta. Bul. 83 (1915), pp. 30, figs. 10).—This bulletin, which supplements an earlier one of the station (E. S. R., 21, p. 14), reports "the results of a study of meteorological phenomena at different heights, undertaken with the object of determining, if possible, the value of upper-air data in forecasting frost. The material employed chiefly consists of records obtained simultaneously on the summit of Mount Rose and at stations in near-by

valleys. Analyses of these records have been compared with results of similar researches conducted elsewhere."

Summarizing the results the author concludes that "the general relation or connection between the conditions recorded at the summit and base stations of Mount Rose appears to be practically the same as that found to exist between the summit and base stations of mountains in other parts of the world. Of the decided falls of temperature or cold waves occurring on the summit during four years of observation, about one-half were accompanied by nearly synchronous changes at the base stations; one-third were followed within 48 hours by lower minimum temperatures at the base stations; one-fifth were followed by a slight rise of temperature at the base stations. In the instances where cold waves on the summit precede those at the base, particularly those where a rise of temperature occurs at the base, the cause is probably local gradients less steep than usual, mechanical cooling of the air at the summit during a strong wind, or clouds or fog in the valleys and below the summit. Such a condition, however, does not appear to be a very stable one and probably can not exist very long. Abnormal falls of temperature or cold waves occur most frequently when a cyclone or area of low pressure is about 500 miles south or southeast, and an anticyclone or area of high pressure about 300 miles northwest of Mount Rose. When well-defined cyclones and anticyclones pass over or near Mount Rose, the changes of temperature at the summit and base are nearly synchronous, for at such a time the winds at all levels are higher than normal and the atmosphere more nearly homogenous."

While the author believes that data from high-level stations, such as are reported in this bulletin, will be found valuable in local forecasting, they should be supplemented by determinations, in some level region, of "the vertical gradients or distribution of the chief meteorological elements by means of recording instruments elevated by kites and balloons and from observations of the formation and movements of clouds. . . . Comparisons of free-atmosphere data with observations on mountains and in valleys under various conditions of weather will show the relation of local phenomena to the general movements of the atmosphere."

It is urged that the practical utility of the results of such investigations can be greatly increased by embodying the information in courses of instruction.

Report of the chief of the Weather Bureau, 1915 (U. S. Dept. Agr., Weather Bur. Rpt. 1915, pp. 276, pls. 4).—This report follows the general lines of previous years (E. S. R., 32, p. 810).

Among the subjects of special interest briefly discussed in the summary report are the progress and present status of snow surveys in mountain watersheds in Utah, Idaho, Wyoming, and Arizona which are being carried on as a means of measuring the water which may later be available for irrigation; a preliminary trial of a scheme of utilizing amateur wireless operators in the distribution of weather forecasts; improvement of the system of storm warning signals on the Great Lakes; and observations on the extent and damage caused by floods.

"The heavy and continued rains of May and June, 1915, in Kansas, Nebraska, and adjoining sections, while not producing marked floods in the rivers, nevertheless wrought immense damage to standing crops, not only from overflow and total destruction along the rivers and small streams, but also by reason of the saturated condition of the soil, it being impracticable to gather crops until the ground dried out. An estimate of the damage to crops and farm lands in Kansas places the amount at \$6,000,000, with an additional \$1,500,000 along the Missouri east of Kansas City."

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 3 (1916), Nos. 3, pp. 239, pls. 2, figs. 6; 4, pp. 228,

pls. 2, figs. 6).—These numbers contain, respectively, brief summaries and detailed tabular statements of climatological data for each State for March and April, 1916.

Climatology of State College, Pennsylvania.—II, Precipitation (rain and snow), W. Frear (*Pennsylvania Sta. Rpt. 1914, pp. 233-347*).—This is an elaborate discussion of precipitation at State College, Pa., based upon observations from 1880-1913, inclusive. It supplements a similar discussion of the temperature of this place published in a previous report (E. S. R., 34, p. 115).

The records show that the locality belongs to the common class as regards hours of greatest rainfall frequency, namely, that in which rains are least frequent in the hours immediately preceding noon. "The larger precipitation in the afternoon as compared with the morning division of the late spring and summer days is due both to the greater frequency of the rainfall at that time of day, and also to the greater average quantity of the afternoon as compared with the morning rains. In like manner, the night time precipitation is on the average greater than that at other times of day during the remainder of the year, and for the same reason—that the night rains are then the more frequent and more copious." The summer daytime precipitation is about one-half greater than that occurring by night when the total precipitation through the period is considered.

"Considering the number of rainy days in the year, as indicated by the occurrence of measurable precipitation, 1886 with 99 days had the least, and 1911 with 157 days, the most. The average for all years was 130.3 days, or about 4.3 days out of twelve."

The largest precipitation occurred in the summer months; the smallest in the winter. The data give no support to the popular idea of the relation of rainstorms to holidays or to equinoxes.

The average annual rainfall for the period was 39.762 in., and this was distributed by seasons approximately as follows: Winter 8.82 in., spring 10.52 in., summer 11.76 in., and autumn 8.38 in. There was no regularity of annual precipitation. "Of the 30 years for which the records are complete, the annual total falls below the average in 13 cases, and exceeds it in 17 cases. The extreme range is from 30.845 in. in 1887 to 46.545 in. in 1891, a range of 15.7 in., which is more than half of the minimum. The mean between the extremes is 38.695 in., or 1.067 in. below the average." For one-half of the years the annual average was above 40 in.

As regards unsettled weather the winter and spring months showed the greatest frequency and the summer months least. Dry spells, that is, periods of 14 days or more in which less than 0.1 in. of rain fell, were very irregularly distributed among the months, but the last four months of the year showed them in the greater frequency. "That is, the dry spells are most frequent at the season when the number of crops that can be directly affected is least. May stands next in the order of frequency, and represents a critical period in the life of the majority of farm and garden crops, but June had but one dry spell in the thirty years for which the detailed records are at hand; so that it tends, on the average through many years, to compensate for the May fickleness of water supply."

The average seasonal snowfall for the period was 47.18 in. It ranged from 18.01 in. in the winter of 1888-89 to 83.14 in. in the winter of 1907-08. The greatest snowfall of a single month was that of February, 1908, when 41.8 in. fell. The ratio of rainfall to snowfall of the winter season was as 74 of the former to 26 of the latter. The greatest snowfall in any one day was 17.5 in., March 5, 1902.

Meteorology for 1913, H. D. Edmiston (*Pennsylvania Sta. Rpt. 1914*, pp. 390-399, 497-518).—The observations here recorded are of the same character as those reported in previous years (E. S. R., 34, p. 118). The summary for 1913 is as follows:

Summary of meteorological observations at State College, Pa., 1913.

Kind of observation.	1913	Growing season (April-September).
Barometer (inches): Mean. Temperature (°F.): Mean. Highest Lowest. Greatest daily range. Least daily range. Rainfall (inches). Number of days on which 0.01 in. or more rain fell. Mean percentage of cloudiness. Number of days on which cloudiness averaged 80 per cent or more. Last frost in spring. First frost in fall.	4.0 (Feb. 2, Mar. 7) 37.0 (June 11) 33.0 (Apr. 28, Dec. 3) 39.83 127 49.4	25.0 (Apr. 8).

Ohio weather for 1915, J. W. SMITH and C. A. PATTON (Ohio Sta. Bul. 296 (1916), pp. 349-428, figs. 61).—The temperature and precipitation throughout the State during each month are shown in charts. The usual summary tables are given showing temperature and rainfall at Wooster and throughout the State (1888 to 1915).

The mean temperature for the year at Wooster was 48.9° F.; for the State, 50.8°. The highest temperature at the station was 91°, July 16; for the State, 99°, July 31. The lowest temperature at the station was —13°, January 24; for the State, —22°, January 24. The annual rainfall at the station was 42.06 in.; for the State, 40.83 in. The number of rainy days at the station was 132; for the State, 123. The prevailing direction of the wind was southwest at the station and in the State at large.

### SOILS-FERTILIZERS.

Soil survey of Polk County, Georgia, D. D. Long and M. Baldwin (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 46, fig. 1, map 1).—This survey, made in cooperation with the Georgia State College of Agriculture and issued July 5, 1916, deals with the soils of an area of 200,320 acres, comprising parts of the Appalachian and Piedmont Plateau provinces in northwestern Georgia. The greater part of the county is rolling to hilly. Drainage is said to be generally well established. The soils of the area are of residual, alluvial, and colluvial origin. Exclusive of rock outcrop, 31 soil types of 16 series are mapped, of which the Clarksville gravelly loam and the Talladega slate loam cover 33 and 10.1 per cent of the area, respectively.

Soil survey of Jessamine County, Kentucky, R. T. Allen (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 20, fig. 1, map 1).—This survey, issued June 24, 1916, deals with the soils of an area of 110,080 acres in the bluegrass region of east-central Kentucky.

"In the southwestern part the county is hilly and broken, while the northern section is predominantly gently rolling. . . . In general the county is well drained." "The upland soils . . . comprising about 95 per cent of the area, are residual from limestone, except in some comparatively small areas

in the southwestern section, where they are derived from sandstone." Including rough stony land, seven soil types of five series are mapped, of which the Hagerstown silt loam covers 77.8 per cent of the area.

Soil survey of Gage County, Nebraska, A. H. Meyeb, R. R. Buen, and N. A. Bengtson (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 42, fig. 1, map 1).—This survey, made in cooperation with the Nebraska Soil Survey and issued June 10, 1916, deals with the soils of an area of 547,840 acres in southeastern Nebraska lying entirely within the glaciated part of the Great Plains province.

"The topography ranges from almost flat or plainlike to rolling, with steep to abrupt slopes along drainage ways, bordered by rather high rock ledges. As a whole the county is well drained." "The soils of the county are classed, on the basis of origin and mode of formation, into four principal groups, (1) soils derived from loess, (2) soils derived from glacial drift, (3) residual or or partly residual soils, and (4) alluvial soils." Excluding meadow, ten soil types of ten series are mapped, of which the Carrington, Grundy, and Wabash silt loams cover 51.4, 18.4, and 14.7 per cent of the area, respectively.

The soils and agricultural development of northern New York, E. O. Fippin (Cornell Countryman, 13 (1916), No. 7, pp. 570-575, figs. 4).—This article deals briefly with the soil characteristics and agricultural conditions of an area of approximately 14,500 square miles, including all of eight counties and parts of six counties in northern New York. The topography is that of a great central mountainous dome receding to low plains. The soils consist of non-agricultural mountain soils, lowland soils, and lake and terrace soils. It is stated that drainage is the most pressing need of these soils and that liming is also necessary.

Soil survey of Wake County, North Carolina, L. L. BRINKLEY, N. M. KIRK, R. T. ALLEN and B. B. DERRICK (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 45, fig. 1, map 1).—This survey, made in cooperation with the North Carolina Department of Agriculture and issued June 30, 1916, deals with the soils of an area of 537,600 acres lying in the Piedmont Plateau and Coastal Plains regions in central North Carolina. The topography ranges from level to hilly and broken. The county is said to be well drained. The soils are of residual and sedimentary origin. Twenty-two soil types of nine series are mapped, of which the Cecil sandy loam, Durham coarse sandy loam, and Cecil coarse sandy loam cover 21, 14.3, and 10.4 per cent of the area, respectively.

Soil survey of Geauga County, Ohio, C. N. Mooney, H. G. Lewis, C. W. Shiffeler, and O. Gossard (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 37, fig. 1, map 1).—This survey, made in cooperation with the Ohio Experiment Station and issued June 30, 1916, deals with the soils of an area of 263,680 acres in the Allegheny Plateau region in northeastern Ohio. The surface varies from flat or nearly flat to gently undulating or rolling and hilly.

"The soils are predominantly silty. They are of glacial origin and derived largely from sandstones and shales of Carboniferous age. According to topographic position and mode of formation the soils fall into three general groups—glacial upland, or unmodified till soils; glacial-lake and river-terrace, or modified till soils; and river flood plain or alluvial soils, with muck and peat, a cumulose formation." Including muck and peat, 16 soil types of eight series are mapped, of which the Volusia clay loam and loam cover 61.7 and 11.4 per cent of the area, respectively.

Some alkali soils in Ohio, J. W. AMES (Mo. Bul. Ohio Sta., 1 (1916), No. 7, pp. 209, 210).—It is stated that the areas of alkali soils in Ohio are located in the southern part of Highland County and in Brown and Clermont counties. Examination of the alkali soil in one case showed contents of magnesium, aluminum, and sulphur equivalent to 4.27 per cent magnesium sulphate and 4.9 per cent aluminum sulphate.

Soil survey of Frederick County, Virginia, J. B. R. DICKEY and W. B. COBB (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 48, pls. 4, fig. 1, map 1).—This survey, issued June 22, 1916, deals with the soils of an area of 274,560 acres in northern Virginia. The county is divided into valley and hill regions, the topography of the former being undulating to rolling. The hill country has excellent surface drainage.

The soils of the county fall into three broad general divisions. "The most extensive division comprises the soils of the Appalachian Mountain province, or the soils derived from shales and sandstones, while the most important agriculturally is that group of soils found in the limestone valley province, All the soils in these provinces are, with possibly one exception, residual. . . . The third division includes the alluvial soils." Including rough stony land, 19 soil types of nine series are mapped, of which the Dekalb gravelly loam, Berks shale loam, and Hagerstown clay loam cover 24.3, 18, and 10.1 per cent of the area, respectively.

The loess soils of the Nebraska portion of the transition region.—I, II, F. J. Alway et al. (Soil Sci., 1 (1916), No. 3, pp. 197-258, pls. 3, figs. 6).—Two papers are presented.

I. Hygroscopicity, nitrogen, and organic carbon, F. J. Alway and G. R. McDole.—Studies, made at the Nebraska Experiment Station, of the hygroscopicity and nitrogen and organic carbon contents of 648 samples of soils, representing the first six foot sections and the 12 inch sections of the surface foot from five virgin prairie fields in each of six areas in Nebraska located between the Missouri River and the western limit of the loess region in which the annual precipitation decreases from more than 30 in. in the east to less than 20 in. in the west and the relative aridity exhibits a still greater range, are reported.

It was found that "the hygroscopicity, as expressed by the hygroscopic coefficient, is strikingly uniform both from field to field in any one area and from the surface downward in the same field. It is lowest in the two western areas and highest in the two eastern. When the different levels from the individual fields are compared, the highest is found in either the second or the third foot, in which two it is very similar. The minimum value is found in the surface foot of the three eastern areas, and in the sixth of the three western. . . .

"The effect of the organic matter upon the hygroscopicity is too slight to be detected, a change of even 100 per cent in the content of this being without distinct influence. The nitrogen content in all the fields decreases from the surface downward. In the surface foot . . . it decreases steadily, there being in general about half as much in the twelfth as in the first inch section. The nitrogen in the surface foot decreases by about 50 per cent from the most easterly to the most westerly fields, the difference being such as to permit a definite grouping of the areas. The most easterly areas show as high a content in the second foot as do the most westerly in the first. In this level also there is a decrease from east to west, but it does not show the gradual change exhibited in the first foot. In the . . . third to sixth foot . . . the differences are small. . . . The organic carbon in the surface foot is very similar in distribution to that of the nitrogen. The amount of the former is approxi-

mately twelve times that of the latter, the ratio being uninfluenced by the aridity of the climate. When the inch sections of the surface foot are considered the organic carbon decreases slightly more rapidly than does the nitrogen, the average ratio being 13.4 for the first and 11.3 for the twelfth inch section. In the levels below the first foot also a similar difference in the rate of decrease is observed, the ratio in some cases falling as low as 6. The decrease is less rapid in the western than in the eastern areas, the average organic carbon content in the fourth, fifth, and sixth feet being higher in the two most westerly areas than in the two most easterly, while that of the nitrogen is lower. The decrease in nitrogen and organic carbon in the surface soil from east to west . . . [is] attributed to the greater vegetative growth without a correspondingly more rapid decay in the eastern areas.

"The water of constitution (the difference between volatile matter and organic matter) decreases from east to west, the variations being concordant with those in the hygroscopicity. Compared with the Russian chernozem soils formed on loess, the organic carbon and the nitrogen are low both in the surface soil and in the subsoil, the amounts found in the eastern areas being similar to the minima reported for the chernozem. The subsoils from the semiarid areas, in so far as the nitrogen is concerned, in contrast with the arid subsoils, are as 'raw' as those from the humid areas, not supporting a satisfactory growth of nonleguminous plants."

A list of 26 references to literature bearing on the subject is appended.

II. Humus, humus-nitrogen, and color, F. J. Alway and M. J. Blish.—In this report of studies of the humus-nitrogen and color of the soils described in the foregoing article, "the gravimetric method for the determination of humus was found in the case of the subsoils to fail to indicate the relative amounts of ammonia-soluble, dark-colored organic matter present. A colorimetric method is preferable for the subsoils; in the case of the surface soils it is at least fairly satisfactory for the determination of the whole of the ammonia-soluble organic matter.

"Within the surface foot the humus decreases from the first to the twelfth inch and from east to west. The rate of decrease downward is independent of the degree of aridity. In the second foot the decrease from east to west is less marked than in the first, while in the still lower levels the humus, as determined gravimetrically, shows no distinct change from east to west. No marked differences in the percentage of nitrogen in the humus were found between the soils from the most humid and those from the most arid parts of the region. The soluble pigment in the surface foot was found to decrease in passing from east to west, while that in the third to sixth foot increases. A relatively low amount in the surface foot with a relatively high content in the subsoil characterizes the soils from the more arid portion of the region.

"The colors of the soil and subsoils agree in general with the amounts of soluble pigment found by the colorimetric method. . . . The color of the soils in the western areas is lighter, and in all the areas the dark-colored surface layer is shallower than in the typical Russian chernozem. Buried soil surfaces as well as the dark tongues and veins, common in the Russian chernozem, appear to be absent in the loess of the Nebraska portion of the transition region. Gravimetric determinations show the humus of the soils of the western semarid areas to be similar in amount and in distribution to that of typical arid California soils."

A list of 12 references to literature bearing on the subject is appended.

[Composition of caliche], A. E. Vinson and C. N. Catlin (Arizona Sta. Rpt. 1915, pp. 567, 568).—Analyses of five samples of caliche are reported, the results

of which are taken to indicate that this soil is well supplied with potassium and phosphorus and that its potassium-sodium ratio is similar to that found in limestone.

Soil colloids, W. T. McGeorge (Hawaii Sta. Rpt. 1915, pp. 36, 37).—Attention is called to the invariable presence of colloidal aluminum hydroxid in Hawaiian soils of high aluminum content. "In all soils which contain iron in excess of alumina, this colloidal gel is never formed."

Absorption and solution of ammonium and phosphate salts, H. Stratmann (Über Absorption und Lösungen von Ammonium und Phosphatsalzen. Diss. Univ. Giessen, 1914, pp. 62, figs. 2).—The work of others bearing on the subject is briefly reviewed, and experiments with a number of soils of different mineralogical origin and composition, including loamy alluvial soils poor in lime, clay, loess, blow sand, stony loam poor in lime, ortstein, marly soil, slaty clay soil, sericite, slate soil rich in potash, weathered gray wacke soil, weathered granite soil, diabase soil, weathered phonolite, basaltic soil, and diluvial sand soil are reported. The purpose was to determine the extent to which the absorptive power of a soil for ammonia and phosphates is influenced by decreasing its content of colloidal material. Solutions of ammonium chlorid and sulphate of concentrations equivalent to 200 cc. of nitrogen per 200 cc. of solution and solutions of monocalcium phosphate, dicalcium phosphate, and diammonium phosphate of a concentration equivalent to 492 mg. of phosphoric acid per 400 cc. of solution were used.

It was found that in mechanical soil analysis the sedimentation of the fine colloidal particles was not a function of the time or the size of the particle, making the results obtained by the decantation method more or less dependent on an unknown factor. The Schön process was found to be more reliable than the decantation process and in modified form was more simple. The absorptive powers of soils of different origin and composition were influenced in a variable manner by the removal of the finest particles, according to the kind of spar sand present. The silicon dioxid present in some basaltic soils, especially in the group of particles of a diameter varying from 0.05 to 0.03 mm., was found to be a new formation from the weathering of bauxite. The components of so-called double silicates were found only in small amounts in many soils of noteworthy absorptive powers. Synthetic silicates could not be characterized as double silicates. Chabazite and stilbite minerals of the zeolite group were found to be acid salts. Kaolin, as an acid aluminum silicate, is considered to be fundamentally different from the amorphous aluminum silicates of the soil. The main substance partaking in soil absorption and exchange of ions is considered to be amorphous aluminum silicate, which is the end product of the normal weathering of feldspar.

The influence of a stand of trees on the content of dissolved salts in an upland moor soil, E. RAMANN and H. Niklas (*Ztschr. Forst u. Jagdw.*, 48 (1916), No. 1, pp. 3-11).—Two years' tests of the concentration of the solutions of an upland peat moor soil supporting a stand of birch, pine, and other trees are reported, using the electrical conductivity method.

It was found that the soluble salt content of the forested soil was generally larger than that of the bare soil and was less only in the fall. The variation in salt content of the soils was the same for both years. The salt content was rather low in May, increased until July, and then decreased until September. It increased in November to its greatest height. Laboratory tests of the dead leaves led to the conclusion that the rise in salt content in the soils in November was due to leaching out of the soluble salts in the dead leaves.

A preliminary statement on the present status of the humus nitrogen problem in arid soils, C. B. LIPMAN (Soil Sci., 1 (1916), No. 3, pp. 285-290).—The author reviews experimental work by himself and others conducted for the most part at the University of California.

The results are taken to indicate that "the method of determining humus nitrogen in the ammonia extract of soils is a seriously faulty one, no matter how much care is employed in boiling the extract with magnesia. The method is so faulty as to deserve immediate rejection by all those who are at all concerned with the correct determination of nitrogen in humus. If the results given are considered in connection with the largest part of the humus nitrogen data furnished by Loughridge [E. S. R., 34, p. 324], there can be no question that the prevalent belief in the high nitrogen content of the humus of arid soils is in error. The facts in hand do not justify any belief in the higher nitrogen content of the humus in either the arid or the humid group of soils over each other."

A list of five references to literature bearing on the subject is appended.

A contribution to the subject of the factors concerned in soil productivity, C. Hoffmann (Kans. Univ. Sci. Bul., 9 (1914), No. 7, pp. 79-99, pls. 5).—Laboratory experiments conducted at the University of Wisconsin with normal peat, sandy, and marsh soils to determine (1) the influence of the growth of pure cultures of soil organisms in sterile soil on the growth of wheat, corn, and clover seedlings in the extract of such soil, and (2) the influence of the growth of corn, oats, and clover in the same soil on pure cultures of bacteria grown in the extracts of such soil are reported.

It was found that "the growth of individual species of bacteria in a soil produces changes in the soil solution which manifest themselves by an increased or decreased development of plant seedlings when grown in extracts made from such soils. Invariably this influence seems to affect the root development rather than the leaf development. In repetitions of the same experiment consistent results are secured as long as all three factors, soil, bacterial species, and crop, are the same. A change of any one factor modifies the results secured. The growth of individual species of crops in a soil produces changes in the soil solution which manifest themselves by an increased or decreased bacterial multiplication in extracts made from such soils. The extracts made from a marsh soil cropped by corn, oats, or clover in all cases stimulated bacterial multiplication. This stimulation was consistently greatest in the case of the corn-cropped soil. In contrast to the marsh, the extracts from the cropped loam and sand soils invariably retarded the multiplication of the bacteria grown in the same. There is a definite relation between the growth of crops in soil and the growth of bacteria therein. . . .

"Owing to the variability of the three factors involved, soil, crop, and bacterial flora, it is impossible to establish any hard and fast laws for all cases."

Incubation studies with soil fungi, S. A. WAKSMAN and R. C. Cook (Soil Sci., 1 (1916), No. 3, pp. 275-284, fig. 1).—Ammonification experiments conducted at the New Jersey Experiment Stations with Mucor plumbeus, Penicillium sp., and Monilia sitophila in pure culture in a gravelly loam soil, using dried blood and cotton-seed meal as ammoniates, are reported.

The results obtained are taken to indicate that "optimum moisture conditions for ammonia accumulation by fungi lie near the physical optimum. The proper incubation period depends entirely upon the organism. A 12-day incubation period is preferable to a shorter one for practical work. A correlation exists between the biological stage of the organism and the periods of ammonia accumulation; the largest amount seems to accompany the periods of spore

germination and the smallest amount the time preparatory to actual spore formation. *M. sitophila* shows the largest ammonia accumulation within the first 3 or 4 days; *Penicillium* sp., between 10 and 15 days; and *M. plumbeus*, between 6 and 10 days. These periods correspond to those of active spore formation for the respective organisms."

Preliminary experiments on some effects of leaching on the soil flora, C. B. Lipman and L. W. Fowler (Soil Sci., 1 (1916), No. 3, pp. 291-297).—Preliminary laboratory experiments conducted at the University of California on the processes of ammonification, nitrification, nitrogen fixation, and cellulose decomposition in clay loam and blow-sand soils when unleached and leached in the presence or absence of 0.1 per cent sodium chlorid, 0.25 per cent sodium sulphate, 0.05 per cent sodium carbonate, or a combination of 0.1 per cent sodium chlorid, 0.05 per cent sodium carbonate, and 0.1 per cent sodium sulphate, are reported.

The results obtained are taken to indicate that "leaching affects the bacterial flora of soils profoundly. . . . This is particularly so for the nitrifying, nitrogen-fixing, and cellulose-destroying organisms. All of these processes appear to be wholly or almost wholly checked by leaching, especially if salts are present prior to the execution of the latter process."

A list of seven references to literature bearing on the subject is appended.

Nitrification in relation to the reaction of the soil, J. W. White (*Pennsylvania Sta. Rpt. 1914*, pp. 70-80, pls. 4).—Studies of nitrification and the nitrate content of acid soils and soils made acid, especially by treatment with ammonium sulphate, are reported, the results of which are taken to indicate that nitrification does not cease in very acid soils. Soil on which corn and wheat failed was found to be liberally supplied with nitrates.

"The absence of nitrates under growing plants is no indication of the inactivity of nitrifying organisms. The variation in nitric nitrogen content of all areas on ammonium sulphate plats is parallel to the unequal distribution of vegetation. An average plat showed 24.91 parts per million of nitric nitrogen in corn stubble, 13.14 parts per million on clover sod, 9.23 parts per million under clover and timothy, and 36.47 under winter wheat."

Applications of burned lime and ground limestone to soil from the plat materially stimulated the activity of nitrifying organisms. Magnesian lime gave higher nitrates than pure lime. Failure of clover, corn, and wheat was "not due to the absence of available nitrogen as nitrates... On the basis of 256 nitric nitrogen determinations, indications are that nitrification is still active on the very acid soils of the ammonium sulphate plats."

The effect of 1.14 in. of rainfall upon the nitric nitrogen and acid content of plat 32, J. W. White (*Pennsylvania Sta. Rpt. 1914*, pp. 67-70).—Studies of evaporation from a soil during a period of drought and of the capillary movement of water-soluble nitrogen and acids or acid salts before and after a heavy rainfall are reported.

It was found that "the 1.14 in. of rainfall penetrated the soil to a depth of 15 in. There was a total loss of 4 per cent of moisture from the surface soil [growing wheat] between August 18 and September 6." The moisture content of the surface 3 in. of soil, as the result of 1.14 in. of rain September 21, increased in corn soil from 7.11 to 18.86 per cent, in clover soil from 8.72 to 17.02 per cent, and in wheat soil from 6.31 to 16.76 per cent. The corn soil "showed an enormous accumulation of nitrates where corn failed. The difference in nitric nitrogen content of the three areas studied is due for the most part to the presence or absence of vegetation.

As the result of the rain there was a loss of nitrogen from the corn soil as follows: 0 to 3 in., 80.75 lbs. per acre; 0 to 6 in., 61 lbs. per acre; and 0 to

24 in., 68.86 lbs. per acre. "Plat 32 shows considerable accumulation of soil acids to a depth of 24 in. At this depth there was found in [the corn soil] 3,221, [clover soil] 1,800, and [wheat soil] 2,500 lbs. per acre 7 in., expressed in terms of calcium carbonate required to neutralize the acids present. The decrease in the acid content of the surface 3 in. before and after the rain was as follows: [Corn soil] 1,661, [clover soil] 1,152, and [wheat soil] 847 lbs. per acre, expressed in their calcium carbonate equivalent."

Stimulating influence of arsenic upon the nitrogen-fixing organisms of the soil, J. E. Greaves (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 11, pp. 389-416, figs. 5).—In addition to the findings noted in a previous report (E. S. R., 32, p. 720), this report, prepared at the Utah Experiment Station, brings out that "arsenic can not replace phosphorus in the vital process of the nitrogen-fixing organisms, but it can in some manner liberate the phosphorus from its insoluble compounds. This may be either a direct or an indirect action. Arsenic stimulates the cellulose ferments, and these in turn react upon the activity of the nitrogen-fixing organisms. The nitrogen-fixing powers of soil extract, of filtered soil extract, and soil dried for some time are only slightly stimulated by arsenic, showing that arsenic acts mainly by the removal of a thermolabile body which occurs in the soil."

Can soil be sterilized without radical alteration? D. A. COLEMAN, H. C. LINT, and N. KOPELOFF (Soil Sci., 1 (1916), No. 3, pp. 259-274, figs. 2).—Preliminary experiments conducted at Rutgers College on clay-loam soil to determine (1) the effect of intermittent sterilization of soil by dry heat, (2) the relative sterilizing efficiencies of volatile chemical substances when used as soil antiseptics, and (3) the effect of volatile antiseptics applied in partial vacuum and under pressure at 80° C., are reported.

It was found that "intermittent sterilization by means of dry heat at 82° for five successive days in moist soil almost completely decimated the bacterial flora of the soil. This was accomplished with but a slight change in the chemical constitution of the soil, as indicated by the amount of water-soluble solids. Ordinary steam sterilization under pressure causes a change 16 times as great. There is a strong indication that the application of volatile antiseptics either in partial vacuum or under a combination of heat and pressure, if repeated for more than three successive days, would achieve complete soil sterilization without involving any radical alteration in the chemical constitution of the soil."

A list of 14 references to literature bearing on the subject is appended. The effect of partial sterilization on plant growth, W. T. McGeorge (Hawaii Sta. Rpt. 1915, pp. 37, 38).—Pot experiments with red clay and a sandy soil high in organic matter growing onions, millet, and cowpeas are reported. "These soils were treated as follows: Heated in sunlight, in an oven at 80, 110, and 165° C., and in an autoclave at 10 lbs. pressure. Those heated in the oven were left for two hours, that in the autoclave for only one hour. In addition, soils were treated with the following antiseptics at the rate of 10 cc. per kilogram: Carbon bisulphid, chloroform, and toluene. . . .

"The influence of partial sterilization upon onions was very marked. Volatile antiseptics produced a [marked] increase, while heating in the autoclave was productive of a substance evidently toxic toward this plant. An increase in vigor of the millet plant was correlated with an increase in temperature at which the soil was sterilized. The plants are more vigorous in the pots sterilized by heat than those sterilized by antiseptics. It appears that the organic substance having a toxic influence upon onions is without effect upon millet, for in the pot heated in the autoclave the plants are as vigorous as any others.

"In case of cowpeas, the increase in temperature at which the soils were sterilized resulted in a steady decrease in vigor. While the volatile antiseptic lowered the vigor to a slight extent, their influence is not so marked as heat. These results clearly show the intimate relationship between leguminous plants and bacterial life in the soil."

Variation in the growth of clover on Mitchell field (A), J. W. WHITE (Pennsylvania Sta. Rpt. 1914, pp. 65, 66, pls. 2).—Studies of the lime requirement, the contents of acid-soluble calcium and magnesium oxids and phosphoric acid, and the total nitrogen of a soil in a field where clover grew both well and poorly showed that the irregular growth of the clover was due to the unequal distributions of basic material which controls the reaction of the soil.

"The growth of clover and the lime requirement are in close accord. No other one factor bears such a close relation to the growth of clover.... [Considering] the sum of the lime and magnesia, which forms the determining factor so far as the reaction of the soil is concerned, the two bear relations parallel to the lime requirement, though in an opposite direction.... The limit of acidity may vary with the fertility of the soil, or possibly with a difference in the kind of free acid present."

Soil management problems (Wisconsin Sta. Bul. 268 (1916), pp. 26-32, figs. 4).—The general results obtained in experiments on the management of silt loam, clay, and sandy soils, the effect of cultivation on soil acidity, the correction of soil acidity with limestone waste from lead and zinc mines, fixation of nitrogen in acid soils, and nitrate formation in different soil types are briefly noted.

[Reclamation of alkali soils], J. H. BARNES (Rpt. Dept. Agr. Punjab, 1915, App., pp. IV, VI-IX).—Studies of nitrogen fixation, ammonification, nitrification, and carbon dioxid production in barren alkali soils at Narwala in the Punjab district before and after mole drainage, cultivation, and flooding with canal water are reported in tabular form, showing a marked increase in bacterial activity following such treatment.

[Soils and fertilizers], N. H. J. MILLER (Ann. Rpts. Prog. Chem. [London], 12 (1915), pp. 211-233).—This section summarizes the results of recent investigations relating to soils and fertilizers.

Effect of fertilizers on soil structure as indicated by the draft of a plow, C. F. Noll (*Pennsylvania Sta. Rpt. 1914, pp. 36-46, pls. 2*).—Dynamometer tests made on plats of clay and silt loam soil, treated since 1882 with commercial fertilizers, lime, manure, lime and manure, and land plaster are reported.

"The plats are divided into four series or tiers of 36 one-eighth acre plats each, on which are grown each year in rotation, in the order named, corn, oats, wheat, and mixed clover and timothy. The dynamometer tests were begun in the fall of 1911 and were repeated each time a tier of plats was plowed. Three series of tests were made in plowing sod, three in plowing corn stubble, and three in plowing oat stubble. . . . On each plat two tests were made at one plowing near the ends of the plats and each was for a distance of about 50 ft."

It was found that "the fertilizer treatment has had little influence on the soil structure. The nitrate of soda applied at the rates of about 160, 320, and 480 lbs. per acre has not materially affected the physical properties of the soil. The draft has been about the same on four manured plats as on complete commercial fertilizer plats alternating with them. The presence of more organic matter in some of the soils has slightly lightened their draft."

Meadow fertilization experiments, M. Stein (Deut. Landw. Presse, 48 (1916), No. 21, pp. 178-180).—Five years' experiments on loamy sand, loam, humus sand, marshy sand, and shallow mountain meadow soils of seven different localities of the Province of Saxony are reported.

It was found that artificial fertilization with potash and phosphoric acid in general improved the quality and increased the yield of the crop. When nitrogen fertilization was also employed, especially on grass, the yield was further increased. Nitrogen fertilization improved grain crops, but continued fertilization with potash and phosphoric acid alone generally became gradually injurious. On poorly drained soils fertilization had little effect.

Fertilizer ratio experiments with grass on Hagerstown loam, C. F. Noll, O. Schreiner, and J. J. Skinner (Pennsylvania Sta. Rpt. 1914, pp. 22-36, pls. 2).—Field experiments in which acid phosphate, sodium nitrate, and potassium chlorid were applied to silt loam soil for four years in 66 different fertilizer ratios of phosphate, nitrate, and potash graded in 10 per cent stages are reported. "The total amount applied on each plat totaled 50 lbs. per acre of the fertilizer elements, P₂O₅, NH₃, and K₂O alone or in combinations of two or three of these. The plats were located in a permanent pasture field where the composition of the pasture was chiefly Canada blue grass, Kentucky blue grass, and timothy with a very little white clover and red clover."

The various phases of the results obtained are presented by means of the triangular diagram employed by the Bureau of Soils of the U. S. Department of Agriculture in solution culture experiments in studies of organic soil constituents (E. S. R., 24, p. 32; 26, p. 224).

it was found that "used alone, nitrate has given a large increase over the untreated plats in yield of hay, while both phosphate and potash have yielded a little less than the checks. With increase in percentage of  $NH_3$  applied as nitrate, the yields have increased, and with increase in percentage of either  $P_2O_6$  or  $K_2O$  the yields have not increased. The plats [receiving] 50 per cent or more of  $NH_3$  as nitrate have considerably exceeded in yield those in the subtriangles which have received 50 per cent or more of  $P_2O_6$  or  $K_2O$ . There has been a slightly greater response from  $K_2O$  than from  $P_2O_6$ . The slight differences in the texture of the soil on the different plats have had little influence on the yields. The depth of surface soil has had a marked influence upon the yield."

Legumes as green manure, W. T. McGeorge (Hawaii Sta. Rpt. 1915, pp. 32, 33).—Pot experiments made by A. R. Thompson with a calcareous soil and a soil poor in lime in which 32 varieties of legumes were grown are reported. At maturity the duplicate plants in two pots were removed, weighed, and the nitrogen content determined. Two pots were left of each variety of legume planted, the plants being turned under to decompose.

"In all instances the [content of] nitrates in the soil from which the legumes had been removed was much lower than in the check soil, but these soils low in nitrates on standing in the open air soon equaled in nitrate value the soil of the check pots. Where much legume material was turned under the nitrates in the soils were greatly increased. The plants grown in soils deficient in lime made a poor growth and had a lower nitrogen content, calculated on a water-free basis, than the plants grown in soils rich in lime. In a second experiment lime was added to the lime-poor soil, but the plants grown in this soil were also undersized and low in nitrogen."

Legume inoculation and nitrogen fertilization on upland moor meadows and pastures, B. Tacke (Mitt. Ver. Förd. Moorkultur Deut. Reiche, 34 (1916), No. 3, pp. 37-47).—Experiments on the possibility and practicability of substituting nitrogen fertilization for inoculation of soil by nodule bacteria for leguminous pasture and meadow crops are reported.

The results are taken to indicate that nitrogen fertilization can replace inoculation only where more or less active nodule bacteria are present in the soil in sufficient numbers and distribution. The substitution of nitrogen

fertilization for inoculation is probably most advantageous in cases where the inoculating substance is difficult to obtain or use at the proper time. Inoculation in every case noted was cheaper than nitrogen fertilization. The advantage of nitrogen fertilization was greater the shorter the time since the soil had been broken.

The influence of the distribution of nitrogenous fertilizers and straw in soil on plant production, B. Niklewski (Ztschr. Landw. Versuchsw. Österr., 18 (1915), No. 12, pp. 674-690).—Pot experiments with oats on a sandy loess soil deficient in plant food to determine the influence of distribution in the soil on the action of sodium nitrate, ammonium sulphate, liquid manure, peptone, and straw are reported.

The influence of nitrogen fertilization on plant production was found to be determined, next to total amount, by its concentration. A greater increase in crop yield was obtained by distributing ammonium sulphate in the soil in a layer than by mixing generally a double quantity with the soil. The favorable influence of distribution in a layer was especially marked when using the smaller amounts, a saving being thereby obtained.

The influence of distribution was found to vary with the speed of diffusion of the different fertilizers in the soil, the greatest influence being evident for peptone and the least by sodium nitrate. The effectiveness of a fertilizer was also found to depend not only on its physiological value but also on its speed of diffusion in soil. The influence of the speed of diffusion of a fertilizer could be diminished by distribution in the soil and the value of the fertilizer thereby altered.

By intermixing with soil in lower concentrations the best results were obtained with sodium nitrate, followed in order by ammonium sulphate and peptone. By placing in the soil in a layer in higher concentrations the best results were obtained with peptone, followed in order by ammonium sulphate and sodium nitrate.

The concentration of the fertilizers appeared to influence strongly the microbiological processes of the soil and also plant development.

The straw had an unfavorable influence on the utilization of ammonium sulphate in lower concentrations and a favorable influence in higher concentrations. This result is considered an important factor in determining the proper use of liquid manure and the availability of nitrogen in stable manure. Straw had a favorable influence on the utilization of sodium nitrate in lower concentrations, but was without influence in higher concentrations. Straw hastened the diffusion of sodium nitrate in soil, especially in lower concentrations.

Pot fertilizer experiments with new nitrogenous fertilizers, M. Popp (Mitt. Deut. Landw. Gesell., 31 (1916), No. 4, pp. 54-57).—Pot experiments with oats on a sandy soil deficient in humus to determine the relative fertilizing values of ammonium nitrate, sodium nitrate, ammonium sulphate, sodium-ammonium sulphate, ammonium bicarbonate, ammonium chlorid, two kinds of urea, urea nitrate, lime nitrogen, and granulated lime nitrogen when added in amounts equivalent to 0.5, 1, 1.5, and 2 gm. of nitrogen per 10 kg. of soil are reported.

With reference to crop yield the best results, not considering lime nitrogen, were given by sodium nitrate, followed in order by ammonium chlorid, ammonium sulphate, urea nitrate, ammonium bicarbonate, ammonium nitrate, urea, and sodium-ammonium sulphate. With reference to both crop yield and nitrogen utilization sodium nitrate again gave the best results, followed in order by ammonium sulphate, ammonium nitrate, ammonium chlorid, urea nitrate, urea, sodium-ammonium sulphate, and ammonium bicarbonate. Urea obtained by synthetic process gave the poorest results in both cases.

It was further found that ordinary lime nitrogen gave considerably less favorable results than ammonium nitrate, while the granulated lime nitrogen in the smallest and medium applications gave results comparable to those obtained by others.

Nitrogen fertilization experiments by the German Agricultural Society in 1914-15, E. RITTER and KLEBERGER (Mitt. Deut. Landw. Gesell., 31 (1916), No. 3, pp. 30-33).—Two sets of experiments with oats, potatoes, and beets on 0.125 hectare plats (about 0.31 acre) of deep mild loam, sandy to loamy gravel, mild sandy loam, and heavy clay soils are reported.

In the first set it was found that the lime nitrogen as a part of the basal fertilizer gave generally better results than ammonium sulphate as part of the basal fertilizer on mild and heavy loam, clay, and gravel soils. The results are further taken to indicate that the use of lime nitrogen as a top-dressing for oats is advisable only when necessary.

In the second set, comparing lime nitrogen with ammonium carbonate, the increase in yield of potatoes and beets was greater with increasing nitrogen additions, little difference being observed between the two nitrogenous fertilizers. The best effects of nitrogen fertilization were observed on the gravelly soil. The starch content of potatoes decreased with increasing nitrogen applications. The number of diseased and imperfect potatoes and beets increased with increasing additions of lime nitrogen, and this is taken to indicate that the use of larger amounts of lime nitrogen should be undertaken with caution and only after preliminary local experiments.

A brief note of experiments on the use of catalytic fertilizers with lime nitrogen is also included.

Experiments with nitrogenous fertilizers at the Finnish moor culture experiment station in 1911 to 1913, A. RINDELL (Finska Mosskulturför. Årsbok, 18 (1914), No. 1, pp. 53-98; abs. in Zentbl. Agr. Chem., 44 (1915), No. 7, pp. 299-302).—Experiments with oats on moor soil which was first burned and then treated with loam soil at the rate of 150 cubic meters per hectare (79.4 cu. yds. per acre) showed that on such soil both sodium nitrate and stable manure markedly increased the crop yield.

In experiments with burned and unburned moor soil, it was found that the burned soil gave the better results the first year but poorer results thereafter. Nitrogen fertilization was found in further experiments to be profitable in both burned and unburned soil.

Experiments comparing sodium nitrate, ammonium sulphate, and carbid nitrogen for oats showed that the fertilizing value of ammonium sulphate was 83 per cent and of carbid nitrogen 64 per cent of that of sodium nitrate on moor soil. Ammonium sulphate was found to be as good a top-dressing for meadow on loam soil as sodium nitrate, while carbid nitrogen gave less favorable results.

The action of gaseous ammonia on superphosphate and the utilization of the so obtained ammonium phosphate, Gerlach (Ztschr. Angew. Chem., 29 (1916), No. 3, Aufsatzteil, pp. 13, 14; No. 5, Aufsatzteil, pp. 18-20).—An ammonium phosphate fertilizer obtained by treatment of superphosphate with gaseous ammonia is described, and pot and plat experiments with oats, barley, and mustard on loamy sand, sandy loam, and sand containing 5 per cent peat are reported, using the ammonium superphosphate mixture and ammonium phosphate obtained by treating the ammonium superphosphate with cold water saturated with carbon dioxid. Analysis of the ammonium superphosphate mixture showed it to contain total nitrogen 7.15 per cent, total phosphoric acid 16.73 per cent, water-soluble phosphoric acid 1.13 per cent, and total lime 24.78 per cent.

It was found in the experiments that the ammonium phosphate gave as good results, both as a nitrogenous and phosphatic fertilizer, as the ammonium-superphosphate mixture.

Availability of mineral phosphates for plant nutrition, W. I. Bublison (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 13, pp. 485-514, pls. 8).—A review of literature bearing on the subject is given, and 3½ years' experiments conducted at the Illinois Experiment Station on (1) the availability of phosphorus in Tennessee brown rock phosphate for wheat, oats, rye, barley, cowpeas, timothy, red clover, and alfalfa, (2) the comparative productive powers of six mineral phosphates for farm crops, (3) the influence of fermenting dextrose and crop residues on the availability of phosphorus in finely ground rock phosphate, and (4) the influence of the size of particles on the availability of phosphorus in mineral phosphates are reported.

It was found that "phosphorus in rock phosphate can be assimilated by farm crops in sand cultures under greenhouse conditions, even in the absence of decaying residues. Crop residues, when employed in conjunction with brown rock phosphates, were beneficial. Tennessee brown rock phosphate, Florida soft rock phosphate, and Tennessee blue rock phosphate in the heavier applications proved superior to South Carolina land rock phosphate, Utah rock phosphate, and Canadian apatite, for oats, clover, and cowpeas when grown in sand. The phosphorus in brown rock phosphate and Florida soft rock phosphate was more soluble in water and in plant-food solutions than the phosphorus in other mineral phosphates. The superiority of these two phosphates over the others tested is shown chiefly by the first crop.

"Chemical analysis showed that the plant-food solutions applied did not appreciably modify the results. The cereals produced as satisfactory yields as the legumes.

"The crop yields tended to increase as the application of rock phosphate increased up to a point where the size of the pots seemed to be a limiting factor, apatite being the only exception. The plants obtained their calcium, as well as their phorphorus, from brown rock phosphates. No better results were secured when calcium carbonate was applied than when rock phosphate alone was used. There was no particular relation between the citric-acid-soluble phosphorus and the availability of these phosphates for plants. Dextrose, when used as a fermentable substance, was harmful.

"The degree of fineness is a factor which determines to some extent the availability of rock phosphate, as indicated by the brown rock."

A list of 32 references to literature bearing on the subject is appended.

Raw rock phosphate v. acid phosphate, C. E. Thorne (Mo. Bul. Ohio Sta., 1 (1916), No. 6, pp. 188-192).—Experience at several of the state experiment stations is reviewed and 20 years' experience at the Ohio Station briefly summarized, from which it is concluded "that raw phosphate rock is a useful carrier of phosphorus and may be used with profit on soils requiring phosphorus; but . . . when raw phosphate and acid phosphate have been used side by side under such conditions as to fully utilize the crop feeding power of the two materials the acid phosphate has generally furnished available phosphorus at a lower cost than the raw phosphate. . . . .

"In the 20-year experiments of the Ohio Station . . . the largest recovery of phosphorus has been three-fourths of that applied in acid phosphate."

The inter-relationships between the constituents of basic slag, S. H. Collins and A. A. Hall (Jour. Soc. Chem. Indus., 34 (1915), No. 10, pp. 526-530, figs. 3; abs. in Chem. Zentbl., 1915, II, No. 8, p. 431).—Plat experiments with hay on soil varying from heavy bowlder clay to medium loam, uniformly

deficient in phosphoric acid but rich in humus, are reported, in which 11 different slags were used as fertilizer at the rates of 50 and 200 lbs. of phosphoric acid per acre. The results of analyses of the slags are also reported, and a correlation of these with the citric solubility of the slags and with the results of the plat experiments indicated that phosphate is the most important constituent of slag, while magnesium, manganese, and iron stand second in importance and are of about equal weight. "There seems much reason for supposing that a balance of the secondary constituents is needed. . . . Medium proportions of magnesia, manganese, and iron are all useful, but extra large proportions harmful."

Experiments on the solubility of the phosphoric acid in Thomas meal in water saturated with carbon dioxid, J. G. MASCHHAUPT (Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands], No. 17 (1915), pp. 97-141, figs. 5; abs. in Chem. Zentbl., 1915, II, No. 10, p. 552).—Experiments with 59 samples of Thomas meal are reported, the ratios of Thomas meal to water used being 1:4,000, 1:2,000, 1:1,000, 1:500, 1:250, 1:125, 1:100, and 1:50.

It was found that the amount of phosphoric acid dissolved from Thomas meal by contact with water saturated with carbon dioxid depended in large measure on the ratio of Thomas meal to water. The more narrow this relation was the stronger was the influence of the free calcium oxid and calcium silicate in the Thomas meal on the solubility of the phosphoric acid. Thomas slag meals of different citrate solubility showed also different solubilities of their phosphoric acid in water saturated with carbon dioxid. Samples of high citrate solubility yielded the greater amounts of phosphoric acid by the carbon dioxid water method. After a certain number of extractions the solubility of the phosphoric acid in the different Thomas meals became uniform.

The amount of calcium not combined with phosphoric acid appeared to be about the same in the different samples tested. The content of the free lime was greater the smaller the citrate solubility, while the content of calcium silicate was greater with greater citrate solubility. It is thought that the varying citrate solubility is only in small part due to the variable content of free calcium. When the free calcium was separated out the solubility of the phosphoric acid by extraction with 2 per cent citric acid and with water saturated with carbon dioxid was increased but the differences in solubility still existed. These differences are attributed to the calcium phosphate itself, which it is thought may exist in a double compound of calcium phosphate and calcium silicate. Further experiments showed that in spite of the smaller differences in citrate solubility important differences in solubility as indicated by the first extraction with water saturated with carbon dioxid could enter.

The results are taken to indicate that the relations found between citrate solubility and solubility in carbon dioxid water do not yet show that the citrate solubility can be used to indicate the value of Thomas meal.

Results of geological investigation of phosphorite beds in Russia, 1913, IA. Samoïlov (J. Samoiloff) (Otchet Geol. Izslædov. Fosfor. Zalezheï, 6 (1914), pp. 1-29; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1594, 1595).—Investigations of the phosphorite beds of east and northeast European Russia, central European Russia, and central Asia are reported.

It was found that in the eight Provinces and regions the deposits cover an area of 1,840 square miles. "Adding this area to that discovered in the years 1908-1912, the total area becomes 4,510 square miles, containing not less than 3,300,000,000 tons of phosphorites, reckoning the yield at about 5 cwt. per square yard. These phosphorites may be divided into three groups according

to their phosphoric acid content. The first group, containing from 12 to 18 per cent of  $P_2O_5$ , represents 72.9 per cent of the whole; the second, with from 18 to 24 per cent represents 22.9 per cent; the third group, containing more than 24 per cent, represents only 4.2 per cent of the total. The total quantity of phosphoric acid in this mass of phosphorites exceeds 500,000,000 tons."

Phosphates and dolomites of Johnson County, Tennessee, O. P. Jenkins (Resources Tenn., 6 (1916), No. 2, pp. 51-106, pl. 1, figs. 12).—This report deals with the geology, mineralogy, and composition of the phosphate and dolomite deposits of the county and reports chemical analyses of samples. Some of the principal phosphate rocks contain over 60 per cent calcium phosphate.

"Chemically, calcium forms the base of the phosphate. Fluorin is present in amounts varying from about 1 to 1.5 per cent. Carbon dioxid is also present, in amounts varying from a fraction to nearly 3 per cent, and appears to vary pretty closely with the fluorin. Insoluble siliceous matter runs rather high, while iron and aluminum oxid are not much above the commercial limit, averaging about 5 or 6 per cent.

"The so-called limestones of Johnson County prove to be highly magnesian, and all those analyzed fall well into the class of dolomites, many of which are very high in content of calcium and magnesium carbonate. The dolomites, as well as some of the shales, are shown by analysis to contain from a trace to over 2 per cent lime phosphate... The phosphate rocks occur in many pockets, scattered over the foothills of the main valleys, which lie near Mountain City... It appears that the phosphate is generally too low grade to be of wide commercial use at present."

Experiments with lime and waste carbonate of lime, 1913 and 1914, A. LAUDER, T. W. FAGAN, and J. T. Steele (Edinburgh: Edinb. and East of Scot. Col. Agr., 1915, pp. 10).—Two years' experiments in three different localities with turnips on medium loam soil known to be affected with finger-and-toe disease, to determine the effect of quicklime and waste carbonate of lime when added with complete fertilization at the rates of 1, 2, 3, and 4 tons per acre, are reported.

The results obtained are taken to indicate "that a certain minimum amount of lime must be present in each soil. Beyond this point an increase in the amount of lime gives an increase in the effect. For the soils under experiment this limit may be placed at from 1 to 2 tons per acre. The results confirm those of work carried out elsewhere as to the beneficial effects of ground lime and carbonate of lime on land affected with finger-and-toe [disease]. When waste carbonate of lime is available it may be employed instead of ground lime for neutralizing soil acidity with satisfactory results. It should be applied at twice the rate of ground lime. For land which has not been limed for a considerable time, dressings of 2 tons of ground lime or 3 to 4 tons of the waste carbonate may profitably be given. When once the deficiency in lime in the soil has been made good, dressings of 10 cwt. to 1 ton per acre of ground lime should be applied at regular and frequent intervals, rather than heavy dressings at long intervals."

Effect of quicklime on organic matter in soils, F. E. Bear (Jour. Amer. Soc. Agron., 8 (1916), No. 2, pp. 111-113).—Experiments conducted at the West Virginia Experiment Station with a silt loam soil, used in fertilizer experiments at the station as noted by Bear (E. S. R., 35, p. 22), are reported.

The results show that "in every case the plat receiving quicklime, as compared with the plat receiving a corresponding fertilizer application without quicklime, shows a lower content of both nitrogen and carbon. . . . The results indicate that quicklime does reduce the amount of carbon and nitrogen in the soil."

Experiments with catalytic manures, I. Giannosi (Italia Agr., 52 (1915), No. 10, pp. 455-458; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, p. 1596).—Field experiments with hemp conducted at the Royal Agricultural College at Bologna, Italy, to determine the influence of catalytic fertilizers containing 7.32, 9.32, and 7.08 per cent of manganese tetroxid, when applied in amounts varying from 220 to 305 lbs. per acre, are reported.

The best yield was obtained on a control plat and the poorest on a plat receiving the catalytic manure, but the differences in the results from different plats were so small as to be within the limits of experimental error. It is concluded that the catalytic manure had no appreciable effect.

Composition of some oil cakes used as fertilizer in Tonkin [Indo China], Bloch (Bul. Écon. Indochine, n. ser., 18 (1915), No. 115, pp. 757, 758).—Analyses of ten samples of oil cake are reported, showing contents of nitrogen varying from 1.02 to 4.76 per cent, potash in four cases varying from 0.042 to 0.3 per cent, and phosphoric acid in four cases varying from 0.203 to 1.955 per cent.

### AGRICULTURAL BOTANY.

Starch congestion accompanying certain factors which retard plant growth, B. L. Hartwell (Rhode Island Sta. Bul. 165 (1916), pp. 23).—It having been observed that accumulation of starch in potato vines followed a deficiency of available potassium in the soil, a series of investigations was undertaken to determine whether the deficiency of the element in question might inhibit cell development, causing less demand for starch, or whether potassium was essential as an activator of diastatic action.

As a result of the investigations it was found that an accumulation of starch seems to be correlated in general with conditions which cause a retardation of growth. The different factors which result in the accumulation of starch in the above-ground portion of the plant do not appear to interfere with photosynthesis, but it is thought that they may have some influence on subsequent metabolism.

Potato tuber production above ground, V. VILIKOVSKÝ (Věstník 5. Sjez. Čes. Lék. Přír., 1915, p. 412; abs. in Bot. Centbl., 129 (1915), No. 15, p. 372).—The author supports the view that the formation of tubers on the potato plant above ground is due to the excessive storing of starch. This is to be regarded as not necessarily pathological but as the result of producing starch faster than it can be removed to its more usual situation in the underground tubers.

The origin of anthocyanin pigments, A. Guillermond (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 19, pp. 567-570).—The author discusses the two main hypotheses supported by different investigators regarding the origin of anthocyanin, the one being that anthocyanin pigments result from the transformation of colorless phenol compounds previously formed in the cells and the other that these pigments are formed in place directly as colored products. He agrees with the later views of Combes (E. S. R., 32, p. 824) in holding, as the result of his own investigations (E. S. R., 35, p. 333), that while anthocyanin is in a large number of cases found in the mitochondial body, it may under different circumstances be derived also from the transformation of colorless phenol compounds previously formed in the mitochondria and then dissolved in the vacuolar liquids.

Recent observations on pollen formation in certain monocotyledons, L. Guignard (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 21, pp. 623-625).—Reporting further observed exceptions to the two general modes of pollen formation (E. S. R., 34, p. 525), the author states that the Orchidaceæ may now be

added to the Iridaceæ, as a sufficient number of genera in the former family have been examined to create a strong presumption that the phenomenon of simultaneous quadripartition is general also for this family.

The ripening of seeds in legumes, C. Schneder (Landw. Jahrb., 48 (1915), No. 5, pp. 739-789, pl. 1, fig. 1).—It is stated that during the process of ripening of legumes, before the green color has given place to yellow but not after that stage, there is a partial transformation of materials and transfer thereof to the seeds. This results in a gain of weight to the seeds at the expense of the other portions of the plant, the nonnitrogenous constituents preceding and the nitrogenous materials following. Backward plants show differences in this respect. Different legumes show characteristic ratios as regards their various constituents. While the readiness to germinate is developed early, the germination percentage is increased during the stage of yellowing, which should be completed before gathering the crop, as early harvesting checks the process of after-ripening and lowers the germination percentage.

Parallel tests of seeds by germination and by electrical response, Mary T. Fraser (Ann. Bot. [London], 30 (1916), No. 117, pp. 181-189).—These experiments, undertaken with a view to the further development of the electrical test used by Waller (E. S. R., 13, p. 461) on the germinability of seeds looking to its possible commercial application, are said to have yielded results which were quite consistent throughout the same samples of grain germinated under given conditions. It is stated that variations in electrical response of grains under varied conditions are strikingly paralleled by variations in the germination values. A certain amount of evidence has already been obtained that there is a time of maximal electrical response, probably corresponding to the time when growth becomes established. The electrical response can be ascertained in a much shorter time than the total germinative value. It appears to be possible also to discriminate on the basis of electrical response between live seeds of high and those of low vitality.

Relations between light and germination, G. GASSNER (Ztschr. Bot., 7 (1915), No. 10, pp. 609-661, figs. 2).—This is a series of preliminary studies including the latent influence of light on germination, the influence of desiccation, the relations between light and media favoring or hindering germination, the influence of light as related to seed bed temperature and after-ripening, the effects of previous treatments, the influence of chaff and of the semi-permeable seed coat in the case of Chloris ciliata, and coloration of seed and of medium.

Studies in electroculture, R. TRNKA, B. MYSÍK, and Š. SAJFERT (Věstník 5. Sjez. Čes. Lék. Přír., 1915, p. 408; abs. in Bot. Centbl., 129 (1915), No. 17, p. 448).—It is stated that while experimentation showed an increase of crops as a result of electrical influence, especially when employed during the hours of sunlight, it has not been sufficient to warrant its practical employment.

The influence of radio-activity on dissimilation processes, V. Zdoenický (Věstník 5. Sjez. Čes. Lék. Přír., 1915, p. 431; abs. in Bot. Centbl., 129 (1915), No. 15, p. 378).—It is stated that while concentrated emanations from radio-active material injure living plants, very weak ones favor starch formation. The formation of sugar is said to be possible only when sunlight is added.

Are spore-forming bacteria of any significance in soil under normal conditions? H. J. Conn (New York State Sta. Tech. Bul. 51 (1916), pp. 3-9).—The author states that the spore-forming bacteria, Bacterium mycoides, B. cereus, and B. megatherium, are nearly always present in soil and that they have been considered characteristic and important soil organisms. In nitrogenous culture media, these bacteria grow rapidly and cause a vigorous ammonification,

and for this reason they have been considered important ammonifiers of the soil. A series of tests was conducted to determine the significance of these organisms in the soil, 26 tests being made to ascertain their relative importance in heated and unheated soil infusions.

When the soil infusion was heated before plating to a temperature of from 75 to 85° C., nearly, if not quite, as many colonies of these bacteria developed as when plated from unheated infusions. This temperature is considered high enough to kill the vegetative forms of bacteria, and their constant occurrence in large number is believed to suggest that the bacteria are present in normal soils as spores rather than in the vegetative state. No increase in the total number of these organisms and no decrease in the number of their spores could be detected in soil to which fresh manure was added. These results are considered as casting doubt on the common assumption that these organisms are important ammonifiers in the soil and they raise a question as to what possible soil conditions favor their growth and multiplication.

A possible function of Actinomycetes in soil, H. J. Conn (New York State Sta. Tech. Bul. 52 (1916), pp. 3-11).—In the course of a qualitative study of the bacteria in certain New York State soils, there was recognized a great similarity between the different soils and the relative numbers of Actinomycetes and lower bacteria present, provided the soils were in the same state of cultivation. Later it was found that Actinomycetes were practically always present in greater abundance in old sod soil than in soil recently cultivated. An investigation of this subject has shown that the average ratio between the number of Actinomycetes in neighboring sod and cultivated spots of the same soil type is slightly more than 2:1. In a study of three neighboring spots in a single soil type, it was found that Actinomycetes colonies not only appeared in greater numbers from sod than from cultivated soil but also appeared in greater numbers from old sod than from sod only two or three years old. The reason for this difference in numbers has not been learned, but it is suggested that Actinomycetes are active in the decomposition of grass roots.

The number of colonies allowable on satisfactory agar plates, R. S. BREED and W. D. DOTTERRER (New York State Sta. Tech. Bul. 53 (1916), pp. 3-11).—Attention is called to the importance in making bacteriological counts of the limit in the number of colonies that may be allowed to grow on a plate without introducing serious errors, and the authors present the results of an investigation testing the standard methods for bacterial milk analysis as adopted by the American Public Health Association and as modified in its meeting of 1915 (E. S. R., 35, p. 70).

The work reported includes a study of the counts made for a large number of agar plates incubated for five days at 21° C., and of some of the same plates after two days' additional incubation at 37°. The results obtained indicate that for milk analysis counts made from plates having more than 30 and less than 400 colonies are very nearly as satisfactory as those made from plates having more than 40 and less than 200 colonies.

A comparison between agar and gelatin as media for the plate method of counting bacteria, H. J. Conn and W. D. Dotterer (New York State Sta. Tech. Bul. 53 (1916), pp. 12-15).—A comparison has been made between the counts obtained from 641 agar plates and 599 gelatin plates inoculated with various samples of soil, and the results show that the discrepant counts are as likely to occur with one medium as with the other. The remarkable agreement between the two media is believed to indicate that the nature of the medium used has little or no influence in producing the occasional widely discrepant counts which occur.

### FIELD CROPS.

[Experiments with field crops], A. M. McOMIE (Arizona Sta. Rpt. 1915, pp. 518-528, figs. 4).—Of 13 varieties planted as spring wheat, California Club produced the largest yield, 38 bu., and Turkey Red the lowest, 14.5 bu. per acre. Chul and Early Baart yielded each 36 bu. per acre and Blue Stem 35.3 bu. Red Chaff ranked first with 55 bu. per acre among 15 varieties sown the latter part of October, being followed by Blue Stem with 53.9, Turkey Red with 51. and Kofoid with 50 bu. per acre. In this list of varieties, Marquis produced 47.8, Early Baart 47.8, Red Fife 47.5, and Red Russian 47.3 bu. In every case fall-sown wheat outvielded the spring-sown and was also less subject to rust.

Sixty-day and Texas Red oats also gave better yields from fall than from spring planting. Black Eagar is described as a variety with black, oval, large, and heavy seed, an exceptionally long panicle, wide coarse leaves, and heavy, canelike stems, and as maturing readily at an elevation of 7,000 ft., where the growing season is very short.

Utah Winter, C. I. No. 592, produced the heaviest yield of 10 varieties of spring-sown barley, being followed by Mariout and Blue Hull-less. Black Winter emmer and spelt, both fall sown, yielded 3,630 and 2,970 lbs. per acre, respectively.

Of 25 varieties of corn under test, Sacaton Mexican June led in yield with 99 bu. per acre. Mexican White Flint and White Dent each yielded 85 bu., while some of the varieties fell as low as 10 bu.

The results of tests with Sudan grass showed that this crop is capable of maintaining 20 sheep per acre continuously for 100 days. In a comparison with Club Top, Sumac, and Amber cane for forage. Sudan grass gave a yield of 16,920 lbs. of dry hay and Club Top, the best of the other three varieties, 14,000 lbs. per acre. The leading grain-producing sorghums for the year were Shallu, Dwarf Black Hulled White Kafir corn, Yellow milo maize, and White milo maize.

Winter vetch gave a dry product of 13,400 lbs. and spring vetch of 16,750 lbs. per acre. A yield of 24 tons of sugar beets per acre is recorded for a planting made November 14, as compared with nearly 8 tons for a planting made February 9. The November plantings consistently exceeded the February plantings for the last four years. A yield of a little over 2,000 lbs. of sugar-beet seed is reported. Twelve varieties of flax ranged in yield from 83.5 to 36.5 bu. per acre. The leading variety of millet was Kursk.

The best success with winter grains of any so far experienced at the Snow-flake dry farm was obtained the past year, the yields ranging from 12 to 32 bu. per acre, with Turkey Red and Marquis leading in production. A yield of about 1.100 lbs. of seed per acre was secured from the Tepary bean, while Pink and Boetcher also gave good yields.

At the Sulphur Spring Valley dry farm October seeding of small grains gave better yields than later seeding. Marquis wheat produced the largest yield, 19.8 bu. per acre, while Turkey Red, Red Chaff, Early Baart, and California Club also proved satisfactory. Barley and rye were found valuable as winter pasture crops, and both produced grains after being pastured. Spring varieties of grain seeded March 15 practically failed. Notes are given on the production of crops on shallow soil underlaid with caliche and on deep soils with clay and a porous or soft caliche subsoil.

The crops succeeding best at this farm during the past two years were Kafir corn, Shallu, Club Top, and other saccharin sorghums; Whippoorwill cowpeas; Sudan grass; and Mexican June, White Wonder, Sherrod, Freid, White Flint,

and Diamond Joe corn. These crops succeeded best when planted from April 1 to May 15.

Notes are given on the production of beans, corn, wheat, emmer, and potatoes at the Prescott dry farm. The leading varieties of beans were Colorado Pinto, Bates, Boetcher, and Tepary, mentioned in decreasing order of yield. Sudan grass produced 3.5 tons of dry hay per acre from two cuttings, in addition to a pasture crop. On bottom land a yield of 3 tons was secured from the first cutting and  $2\frac{5}{8}$  tons from the second, but there was no pasture crop. These plats were planted in rows 42 in. apart. Sudan grass sown with a grain drill failed to reach a height sufficient for cutting. A yield of 3 tons per acre of this grass is also recorded for the high plateau sections, where it was grown at an elevation of about 7,000 ft.

[Breeding work with field crops], G. F. FREEMAN and J. C. T. UPHOF (Arizona Sta. Rpt. 1915, pp. 533-538, fig. 1).—In variety tests with alfalfa at Yuma the hairy type of Peruvian gave the best yields. From the cutting made March 23, 1915, this type of alfalfa produced 5,500 lbs. of hay per acre as compared with 4,738 lbs., the average of the other varieties in the test. The corresponding figures for the cutting made December 8, 1915, were 2,217 and 1,701 lbs., respectively.

An average yield per acre of 1,810 lbs. of green beans was secured from 17 pure races of Tepary beans grown at the Yuma date orchard, the highest yield being 2,526 lbs. for race No. 48. Fifteen lbs. of wild Tepary seed was planted in field plats at Yuma for comparison with the domesticated form as a hay crop. On one plat this seed yielded at the rate of 5,080 lbs. of air-dry hay per acre and on another at the rate of 6,180 lbs. In this test pure race No. 17 yielded 9,760, 6,795, and 5,882 lbs. and Whippoorwill cowpeas 5,960 lbs. per acre of air-dry hay.

A yield of cleaned wheat of 42.91 bu. per acre was secured at this point. As compared with the yield in 1914 this was an increase of 5.24 bu. per acre, which is thought probably due to turning under a few weeks before seeding the wheat in the fall a green manure crop of Tepary beans yielding approximately 15,000 lbs. of green material per acre. In a test of varieties Turkey Red yielded at the rate of 57 bu. per acre, but the averages for all the field plats were as follows: Sonora 51.7, White Algerian Macaroni 44.6, Red Algerian Macaroni 44.6, Early Baart 43.3, and Turkey Red 43.2 bu. per acre.

Among 63 pedigree increase plats from the selection of the best head rows of the preceding year the White Algerian Macaroni strains gave an average of 11.4 bu, per acre more than the average for the other strains. It was observed in connection with this work that certain strains of Turkey wheat, all of which were hard when grown in the Central Plains States, immediately became soft when grown in Arizona under irrigation, while other strains from the same original sources have remained hard. It was also found that on the average those strains becoming soft immediately were greater yielders than those which resisted the softening effect of the climate, but a few pure races of hard Turkey wheat were found which were high yielders and at the same time maintained their hard, glutenous texture.

Report of the agronomy department, C. A. Sahr (Hawaii Sta. Rpt. 1915, pp. 39-44, pls. 2).—Deep plowing of soil and allowing it to aerate from one to several months before planting rice and taro gave increased yields in every test, although in the case of taro the increase was small. Potatoes on soil with 16 per cent of water in the upper 6 in. failed to sprout properly, while soil with 24 per cent of moisture produced plants. In a spraying test the check plat yielded 15 bu., the plat sprayed with lime-sulphur 25.9 bu., and the one sprayed with Bordeaux mixture 30.2 bu. of tubers per acre.

Notes are given on culture tests with clover, sweet clover, Crotalaria mesopontica, C. madurensis, C. incana, C. striata, Stizolobium hassjoo. S. cinereum, and S. capitatum. Jack beans and species of velvet beans sown early in September gave the best yields of both green substance and seed. The following annual yields of green forage from different varieties of alfalfa are reported: Spanish 56,362 lbs., Kansas common 52,065 lbs., Utah common 45,245 lbs., Peruvian 35,530 lbs., and Turkestan 30,595 lbs. per acre. Semipalatinsk alfalfa (Medicago falcata) did not prove equal to common alfalfa or Japan clover (Lespedeza striata).

The total yields of green forage per acre for a period of 26.5 months for the sorghums and 27 months for the Japanese cane are recorded as follows: Sweet sorghum, 8 cuttings, 86.55 tons; nonsaccharin sorghum, 6 cuttings, 88.45 tons; and Japanese cane, 3 cuttings, 157.64 tons per acre. The results with other varieties of sorghum are also noted.

Of the several forage grasses on trial, Sudan grass retained its lead in the production of green forage, yielding at a low elevation an average of 14.5 tons per cutting per acre for 7 cuttings as compared with an average of a little less than 4 tons per acre for 6 cuttings for Tunis grass. The value of other grasses, including molasses, Wilder, Australian blue, Giant Bermuda, teff, Mitchell, wallaby, side oat grama, Judd, and American buffalo grass, is briefly mentioned. Japanese millet is reported as maturing at the station in 80 to 100 days under ordinary conditions and as yielding about 10 tons of forage per acre when cut green and 3 tons of roughage and 30 bu, of seed per acre when left to mature. The best results in controlling the spread of Japanese nut grass were secured by spraying with arsenite of soda.

Japanese buckwheat was found to mature a week earlier than Silverhull and to yield about 25 per cent more grain. The average annual yield per tree for 4 years of Caravonica cotton planted on the station grounds in February, 1910, was approximately 1 lb. of lint. The distribution of seed of cotton and grasses conducted by the department is briefly mentioned.

[Work with field crops in 1915] (Wisconsin Sta. Bul. 268 (1916), pp. 4-6, 10-15, 32, 36, figs. 10).—In connection with the work of the agronomy department with pedigreed strains of rye, an improved strain known as Pedigree No. 1, and excelling in stiffness of straw and milling qualities, was developed from the Schlansted variety. A yield of 46.5 bu. per acre under field trials, or 14.5 bu. over the yield of common varieties, is recorded. A cross by E. J. Delwiche between Minnesota 169 and Red Fife wheat produced a strain with exceptional stooling power, marked resistance to rust, a strong straw, and early maturing qualities. In 30 tests at the station by R. A. Moore and B. D. Leith with wheat, Pedigree No. 2, a type of Turkey Red winter wheat, yielded 49.6 bu. per acre and Marquis spring wheat 43 bu. Milling and baking tests with 21 samples of the 1914 crop showed that Pedigree No. 2 gave fully as good results as the standard spring wheats of highest milling quality. The Wisconsin spring wheats analyzed 12.46 per cent of gluten as compared with 11.05 in the standard spring wheat patent flours.

The work of the station to establish hemp growing in the State, conducted by C. P. Norgord, is described and the progress made in this direction is noted. The results of comparative trials of over 200 strains and varieties of alfalfa by L. F. Graber indicated that the common purple-flowered alfalfa from Kansas and Nebraska seed withstood winterkilling last winter quite as well as alfalfa from northern-grown seed. Pedigree No. 4 and White Jewel outs grown in the Superior district were found by E. J. Delwiche to be the most resistant to the influences causing lodging. Yields of 2.5 to 3.7 tons of hay per acre are reported

as secured in plat tests although the season was unfavorable on account of prevailing low temperatures.

Studies made of the influence of freshly turned under green manures like clover on the germination of seeds rich in oil indicated that germination is injuriously affected by a soil fungus, Rhizoctonia, which is given most favorable conditions of growth through the incorporation of organic matter.

Investigations on the relation of sulphur to plant nutrition were extended to oats and barley which were materially helped, especially in seed production, by an increased supply of sulphates, but the effect was not so marked as with rape and clover. The influence of elemental sulphur, while sometimes beneficial, was found often to exert a poisonous effect.

Relative water requirement of corn and the sorghums, E. C. MILLER (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 13, pp. 473-484, pls. 3. fig. 1).-In work carried on by the Kansas Experiment Station, the water requirement was determined for four varieties of corn and two varieties of sorghum in 1914, and for three varieties of corn and five varieties of sorghum in 1915. The work was carried on at Garden City, Kans., where the plants were grown in large, sealed, galvanized-iron cans containing approximately 110 kg. of soil, having a wilting coefficient of 13 and a moisture content maintained at from 20 to 21 per cent on the dry basis. Three plants of corn were grown in each can during both seasons, and 6 sorghum plants were grown in each can in 1914, but only 3 in 1915. A summary of the data secured in the experiments, which are tabulated in detail, shows the following relative standing as to water requirement of the different crops and varieties for the two years: In 1914, Blackhull Kafir corn 1, Dwarf Milo maize 1.04, hybrid corn 1.09, Sherrods White Dent corn 1.22, and Pride of Saline corn 1.24; in 1915, Blackhull Kafir corn 1, Dwarf Blackhull Kafir corn 1.02, Dwarf Milo maize 1.12, feterita 1.14, hybrid corn 1.17, Pride of Saline 1.23, Sherrods White Dent corn 1.27, and Sudan grass 1.41.

Sorghum and millet, F. A. Welton (Mo. Bul. Ohio Sta., 1 (1916), No. 6, pp. 168-174, figs. 2).—This article discusses briefly the culture and value of sorghum and millet, and reports the yields secured in comparative tests with these crops.

A comparison of corn and sorghum during the four years beginning with 1912 showed that such late varieties of corn as Blue Ridge, Hickory King, and Boone County White produced larger yields of green forage per acre than were obtained from sorghum, while two early varieties, Darke County Mammoth and Leaming, yielded less than sorghum. For the same period average yields of 10, 14, 9.1, 9.9, and 7.6 tons of green forage per acre are reported for Amber sorghum, Orange sorghum, Red Kafir corn, White Kafir corn, and Yellow milo maize, respectively. The average production for seven nonconsecutive years of Hungarian, German, Red Siberian, and Japan barnyard millet tested on the station farm was 2.6, 4.4, 2.8, and 4.8 tons of dry forage per acre, respectively.

Concerning the growth and composition of clover and sorrel (Rumex acetosella) as influenced by varied amounts of limestone, J. W. White (Pennsylvania Sta. Rpt. 1914, pp. 46-64, pls. 13).—Studies on the general fertilizer plats of the station, supplemented by pot experiments, were made with reference to the growth of sorrel as influenced by soil acidity. Work related to this subject by other investigators is briefly reviewed and the results presented in tabular form are discussed. Some of the plats on which the investigation was conducted received ammonium sulphate as the source of nitrogen and showed an increasing tendency to failure of clover and to a less extent of corn and wheat.

In 1912-13 sorrel grew on plat 32 having an acid soil at the rate of 1 ton per acre. In areas where the soil acidity required from 3,500 to 3,800 lbs. of

calcium carbonate per acre to correct it to the depth of 7 in., clover failed and sorrel took its place; where from 4,000 to 4,500 lbs. of calcium carbonate were similarly required, timothy was largely replaced by sorrel; and where the maximum acidity was reached red top predominated. Plats receiving calcium as sulphate and carbonate are reported as free from sorrel.

In the pot experiments the greatest yield of clover occurred where limestone was applied at the rate of 3 tons per acre in excess of the quantity required to render the soil neutral. Clover failed in these tests where the acidity for its correction required from 3,000 to 3,500 lbs. of calcium carbonate per acre for the upper 7 in. of soil. Where limestone was present in slight excess in the pot experiments, sorrel was largely replaced by clover, but it produced the highest yield where the maximum amount of limestone was applied.

The calcium content of clover and sorrel was highest where the largest quantity of limestone was added to the soil. The protein content of clover was found to vary but slightly whether grown in an alkaline or an acid soil. The calcium content of sorrel grown on plat 32 was determined as only 10 per cent of that grown in an alkaline soil. The leaves of sorrel grown on this plat contained 17.92 per cent protein, equivalent in amount to that in clover, and the sorrel contained per ton of dry matter the equivalent of \$9.03 in nitrogen, potassium, and phosphorus as compared with the corresponding value of \$10.97 for clover. The water-soluble acidity of the sorrel from this plat calculated to oxalic acid was found to be as follows: Total plant 1.36 per cent, leaves 2.45 per cent, stem 0.969 per cent, and seed 0.44 per cent, as compared with 0.98 per cent in the whole plant grown on alkaline soil.

On the basis of these results the author concludes that sorrel is not an acidloving plant but has the property of adaptation under soil conditions unfavorable to the growth of most field crops.

Winter injury of alfalfa and clover, C. A. Gearhart (Mo. Bul. Ohio Sta., 1 (1916), No. 7, pp. 199-201).—Data collected in 64 per cent of the counties of the State are reported as showing that 22.7 per cent of the red clover, 22.3 per cent of the mammoh clover, 17.3 per cent of the alsike clover, and 44 per cent of the alfalfa winterkilled during the winter of 1915-16. Grimm alfalfa was found to show no greater resistance to winter conditions than common alfalfa from seed produced in the Northwestern States.

Comparative yields of hay from several varieties and strains of alfalfa at Brookings, Highmore, Cottonwood, and Eureka, A. N. Hume and M. Champlin (South Dakota Sta. Bul. 163 (1916), pp. 282-343, figs. 9).—Historical and descriptive notes are given of a number of varieties and strains of alfalfa and other species of Medicago introduced and tested in South Dakota. Results are reported of comparative trials of several varieties and strains of alfalfa made at Brookings, Highmore, Cottonwood, and Eureka.

The average yield of field-cured hay per acre in the four localities for the three years, 1913 to 1915, was 2,565 lbs. for Vale, 2,532 lbs. for Grimm, and 2,527 lbs. for Turkestan alfalfa. It is not implied that these three strains should be produced to the exclusion of all others, but it is advised that such strains as Baltic S. D. No. 167, Common S. D. No. 12, Kansas Nonirrigated S. D. No. 173, and other strains now successfully grown in the State should not be hastily discarded. Attention is called to the fact that although Turkestan alfalfa is adapted to hay production in South Dakota, the seed of the variety has a much more limited market outside of the State than the seed of other strains. Field trials of strains of Medicago falcata made at Brookings are reported as indicating that the species may not yield as large average amounts of hay as the strains of M. sativa which have been tested.

Correlated characters in maize breeding, G. N. Collins (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 12, pp. 435-454, pls. 9).—This article reports the results of a study undertaken "to determine whether the difficulty in recognizing types of maize is due to a lack of familiarity with the plants or whether there is a fundamental difference between the heredity of maize and that, for example, of cotton." It was thought that the difficulty of recognizing types among maize plants might be due to a lack of sufficient discrimination and that correlations were the rule rather than the exception. The data obtained were afforded by a cross between Waxy Chinese and Esperanza, Chinese and Mexican varieties respectively, with a number of definitely contrasted characters and considered completely isolated from very remote times. given showing the mean of different characters and the coefficient of variation of characters in first and second generation plants, correlation coefficients. and character pairs exhibiting genetic correlations. The following characters are discussed: Hairs on the leaf sheath, tassel characters, tassel exsert, number of erect leaf blades, angle of tassel axis, and one-sidedness or the peculiarity that a number of the upper leaf blades are borne on one side of the plant.

The results are reported as showing that the characters studied, instead of forming coherent groups, are almost completely independent in inheritance. For the purpose of distinguishing different kinds of correlations they are classified as physical, physiological, and genetic, and a method is proposed by which physiological and genetic correlations may be distinguished.

For the study of correlations 11 of the characters most definitely contrasted in the parents were selected and the correlation coefficients of all the combinations were calculated. Of the 55 possible combinations, 20 were found to exhibit significant correlations, but in all but 5 of these correlations are believed to be physiological rather than genetic. No correlation was found between any two characters closer than 0.5, which fact is regarded as offering an explanation of the difficulty of recognizing types in maize.

"This lack of coherence of characters in maize, taken with the fact that to maintain a satisfactory degree of vigor a diversified ancestry must be maintained, would appear to make the method of isolating types inapplicable to this plant. As an offset to the limitation thus imposed, advantage may be taken of the facility with which desirable characters derived from different parents can be combined."

Cooperative fertilizer experiments with corn, 1908–1914, G. S. Fraps (Texas Sta. Bul. 184 (1916), pp. 3-64).—The results secured during the first three years have been previously reported (E. S. R., 25, p. 627). This bulletin deals mainly with the experiments carried on from 1911 to 1914. Tables are given showing the results secured by the different cooperators and the composition of the soils on which the tests were made. The details of each test are briefly noted and the effect of the different fertilizers or fertilizer ingredients is discussed.

During the seven years, 114 experiments were made and in 87 of this number a gain was secured from acid phosphate, in 76 from cotton-seed meal, and in 46 from potash. It is concluded from the data that the soils concerned need phosphoric acid first, nitrogen next, and potash least. Using from 150 to 200 lbs. of acid phosphate the average gain produced was from 5 to 7 bu. of corn per acre. From 30 to 100 lbs of cotton-seed meal, there was an average gain of 0.4 to 3.8 bu., when used in combination with acid phosphate, while with 200 lbs. of cotton-seed meal, alone or with acid phosphate, there was from 5.5 to 7.1 bu. increase, the results being based on only those experiments in which a gain occurred. From 5 to 25 lbs. of muriate of potash per acre, there were produced

average gains of from 2.3 to 3.2 bu. of corn, and with 50 lbs. of muriate of potash, from 2.1 to 5.1 bu. The average gain ascribed to barnyard manure was from 8.3 to 11.5 bu. per acre, or larger than the gains from acid phosphate, cotton-seed meal, or potash salt.

Thomas phosphate used in 12 tests had about 60 per cent of the effectiveness of acid phosphate. In 11 experiments the phosphoric acid of rock phosphate showed about 22 per cent of the effect of the phosphoric acid of acid phosphate. With lime, used in 12 experiments, there was an average gain of 4.5 bu., but no gain in one-half of the tests. When 50 lbs. of nitrate of soda was substituted for 100 lbs. of cotton-seed meal in 49 experiments, the average difference in favor of cotton-seed meal was about 1 bu. of corn per acre. Manure gave profitable results in the greatest number of tests. Acid phosphate alone gave a large number of profitable increases, and cotton-seed meal alone gave nearly the same number. Cotton-seed meal with acid phosphate gave profitable results in 42 per cent of the trials.

Tests of soy beans, 1915, E. H. Jenkins, J. P. Street, and C. D. Hubbell (Connecticut State Sta. Bul. 191 (1916), pp. 14, fig. 1).—This bulletin presents the data gathered in 1915 in continuation of earlier work (E. S. R., 32, p. 633).

Twenty unnamed varieties of soy beans, chiefly new introductions grown in cooperation with the U. S. Department of Agriculture, ranged from 97 to over 150 days in period of growth and from 19.3 to 31.2 bu. of seed per acre in yield. The named varieties tested required from 6 to 15 days longer to mature, produced on the average 1,200 lbs. less of dry forage per acre, and the dry feed contained about 1.1 per cent more protein, as compared with the results of the same varieties in 1914.

The range in yield per acre of 18 varieties grown in 1915 was from 5,672 to 22,477 lbs. of green forage and from 12.5 to 29 bu. of seed. The results of two years' tests of those varieties which grew successfully in both years are reported as indicating that Wilson, Ebony, and Cloud, small, black-seeded varieties, were in both years among the six varieties yielding the most dry matter in the green forage. Tables are given showing the yield and composition of soy-bean forage, alfalfa, and ensilage corn as determined at the station, and the nutrients per ton of ensilge corn, soy-bean forage, and mixtures of the two. It is stated that an average crop of soy beans such as was grown by the station the past two years contains, exclusive of the roots, approximately 4,255 lbs. of organic matter, 131 lbs. of nitrogen, 23 lbs. of phosphoric acid, and 93 lbs. of potash per acre.

Results of field tests by farmers are briefly noted, and an outline is given of a paper on soy beans as a food for diabetics, previously noted (E. S. R., 34, p. 311).

Tobacco experiments, 1913, W. Frear, O. Olson, and H. R. Kraybill (Pennsylvania Sta. Rpt. 1914 pp. 347-374, pls. 12).—The experiments here described were conducted in cooperation with the U. S. Department of Agriculture and with tobacco growers' societies in Lancaster, Clinton, and York counties in the State. Experiments in Lancaster County were conducted to determine the most productive strain of the Connecticut Seedleaf or Broadleaf variety. The collection of strains by elimination based on earlier results was reduced to 10 in number. The object of the work in Clinton County was the determination of the type of tobacco best adapted to the soil and climate of the Clinton-Lycoming tobacco region. The experiments in York County were inaugurated during the year to ascertain the cause of the decrease in burning quality of the tobacco grown. Earlier and similar work with tobacco has been previously noted (E. S. R., 34, p. 142). Meteorological data and notes on crop conditions, together with results bearing on yield, plant measurement, and leaf quality, are presented in tables.

In the strain selection work with Connecticut Seedleaf or Broadleaf tobacco in Lancaster County, the yields of the different filler strains were as follows: Slaughter, F 1, 1,910 lbs., Cooper, R 1, 1,910 lbs., Espenshade, N 1, 1,795 lbs., "Weaver," B 100, 1,738 lbs., Hershey, K 1, 1,719 lbs., Hostetter, D 1, 1,700 lbs., Ober, J 1, 1,643 lbs., Hoover, A 200, 1,624 lbs., Pound, H 100, 1,604 lbs., and Burkholder, A 300, 1,413 lbs. per acre. The results of plant measurements showed that the leaf dimensions presented no close relationship between the leaf expanse and the relative weights of the cured topped plants.

In an experiment on planting distance and topping height for cigar tobacco, plants were placed 28 in. apart in the row in rows 42 in. apart, and 28 in. apart in the row in rows 36 in. apart. The plants were topped at 15 to 17 or 18 leaves for high topping and at 11 to 14 leaves for low topping. Cultivation was continued in each case beyond the stage of leaf spread when it is usually discontinued in practice. In considering the results of the three previous years with those of 1913, it appeared that in all seasons high topping resulted in the highest gross yield, in two seasons high topping and close planting gave a distinctly greater yield, while in the other two seasons the wider planting gave a slightly higher return. Low topping and close planting led to distinctly higher yields in three out of the four seasons. The close planted tobacco in 1913 produced 10.6 per cent of seconds as compared with 8.6 per cent for the wider or normal planting. Of the normal planted tobacco 75 per cent by weight of the leaves were from 22 to 26 in. in length, and of the close planted tobacco only 66 per cent. The high topped plants showed 69 per cent by weight of long leaves known as firsts, and the low topped, 73 per cent. The results for similar spacing and topping tests made in 1913 on a sandy, loam soil in Clinton County are tabulated without conclusions.

Fertilizer experiments were conducted with the Slaughter strain of seedleaf tobacco. Two plats were fertilized with manure alone at the rate of 10 tons per acre, and two with the same application of manure supplemented with acid phosphate and sulphate of potash at the rate of 300 lbs. and 100 lbs. per acre, respectively, in addition. The average yield of the plats treated with manure, acid phosphate, and sulphate of potash was 1,955 lbs. per acre, and the average yield for the plats treated with manure alone, 1,655 lbs.

Several different types of tobacco were grown for a number of years to study the effect of environmental conditions in Lancaster County on their characteristics. The results are reported as showing that the various strains retained their characteristic points of distinction.

Tests in Clinton County on different farms with wrapper and binder strains in 1913 resulted in the following yields: Local Havana 1,605 lbs., Wisconsin Havana 1,497 lbs., Connecticut Broadleaf 1,477 lbs., Local Havana 1,410 lbs., Local Havana 1,395 lbs., Local Havana 1,347 lbs., Connecticut Havana 1,260 lbs., and Local Havana 1,200 lbs. per acre. In tests with other wrapper varieties it was found that seed from shade-grown Cuban planted in the open produced leaves too short and heavy for wrapper purposes. The yields secured in this test were as follows: Halliday Havana, primed, 1,912 lbs., Halliday Havana, cut, 1,425 lbs., Connecticut Havana 1,294 lbs., and Shade-grown Cuban (seed from Connecticut) 750 lbs. per acre.

The influence of suckering upon the yield and quality of tobacco, H. R. Kraybill (*Pennsylvania Sta. Rpt. 1914, pp. 374, 375*).—An experiment was made on two plats to demonstrate the value of suckering tobacco. A difference of 330 lbs. of cured leaf per acre in favor of the suckered plants was secured with a difference in quality in favor of suckering even greater than the difference in yield.

Influence of time of topping upon distance between leaves on the stalk, H. R. Kraybill (Pennsylvania Sta. Rpt. 1914, pp. 375-377).—Observations were made in 1913 upon 64 plants of the Slaughter strain of Pennsylvania Broadleaf similar in size, uniformity, and vigor. Sixteen plants were topped as soon as the first bud was visible, 16 at the stage of development half-way between the time when the first bud had appeared and the time when the first blossom appeared, 16 when the first flower appeared, and 16 were allowed to mature seed. All topped plants were topped to 15 good leaves.

The data presented in tables indicate that the stem continues to elongate even after the first flower appears but that the portion bearing the eighth to the fifteenth leaf makes the greater increase in length. From the time the first bud appeared both portions of the stem seemed to elongate, the portion bearing the first to the eighth leaf making the slightly larger increase. Topping appeared to arrest growth, affecting to the greatest extent the portion bearing the eighth to the fifteenth leaf. A distinct increase in the length of the internodes was observed after the time the first bud appeared, the average increase between neighboring leaves of the first to the eighth leaf being 0.183 in. or 20.8 per cent, and of the eighth to the fifteenth leaf 0.13 in. or 10.4 per cent.

White Burley tobacco, I. S. Cook and C. H. Scherffius (West Virginia Sta. Bul. 152 (1916), pp. 3-20, figs. 6).—Cultural directions, including soil selection and preparation, rotations, transplanting, cultivation, topping, selection of seed plants, harvesting, curing, stripping, and grading are given, and the results of variety and fertilizer tests are reported. The work is in cooperation with the U. S. Department of Agriculture.

Introduced varieties of White Curley grown from selected seed gave promise of proving superior to the standard variety grown in the State. The results of several fertilizer tests indicated that nitrogen influences the yields of tobacco in the State more than does either potash or phosphoric acid. A combination of all three plant food constituents produced the highest average yield, and an application of about 700 lbs. of a high-grade fertilizer containing not less than 4 per cent of nitrogen was found profitable. In one test conducted for two years the use of 10 tons of barnyard manure per acre gave the best results of all fertilizer materials applied. The approximate cost of growing an acre of tobacco, including the use of 1 ton of ground limestone, 200 lbs. each of sodium nitrate and potassium sulphate, and 300 lbs. of acid phosphate was determined as itemized at \$66.50.

Tobacco growing in Canada, F. CHARLAN (Canada Dept. Agr. Bul. 25, 2. ser., pp. 29, figs. 8).—This bulletin discusses in a popular manner the different phases of tobacco culture, such as the selection and preparation of the soil, the use of hotbeds, cultural methods, harvesting, curing, fermentation, and marketing.

Wheat experiments, C. G. Williams (Ohio Sta. Bul. 298 (1916). pp. 447-484, figs. 19).—This bulletin reports the results of experiments with wheat covering the period from 1887 to 1915, most of the work having been done the last 15 years. The experiments included soil treatment, methods of seeding, tests of varieties, variety improvement by means of pure line selection, and milling and baking tests. Most of the work was done on the station farm at Wooster, but results secured at Columbus, at the district experiment farms at Strongsville, Germantown, Carpenter, and Findlay, and at the county experiment farms in Paulding, Miami, Hamilton, and Clermont counties are also reported.

Wheat without fertilizer treatment in a 5-year rotation with corn, oats, clover, and timothy averaged 42 per cent higher in yield, and in a 3-year rotation with corn and potatoes 50 per cent higher than wheat receiving no fertilizers in

continuous culture. As compared with corn, wheat declined less in yield when grown continuously without fertilizers, and as compared with corn and potatoes in 3-year rotations without fertilizers showed greater hardiness and persistence.

In fertilizer experiments 14 per cent acid phosphate was used at the rate of 160 lbs. per acre on wheat and 320 lbs. per rotation at Wooster and Strongsville and of 120 lbs, on wheat and 240 lbs, per rotation at Germantown and Carpenter. Muriate of potash was applied at the rate of 100 lbs. per acre on wheat and 260 lbs. per rotation at Wooster and Strongsville and 20 lbs. per acre on wheat and 40 lbs. per rotation at Germantown and Carpenter. Nitrate of soda and dried blood were given at the rate of 120 lbs. and 50 lbs. per acre, respectively, on wheat, an equivalent of 480 lbs. of nitrate of soda per rotation at Wooster and Strongsville and at the rate of 80 lbs. on wheat and 160 lbs. per rotation at Germantown and Carpenter. Barnyard manure was applied at the rate of 4 tons per acre on wheat and of 8 tons per rotation at Wooster and Strongsville and of 5 tons per acre at Germantown and Carpenter. In arriving at the financial results, corn was valued at 50 cts. per bu., oats at 331 cts., wheat at 90 cts., hay at \$10 per ton, corn stover at \$4, and straw at \$2. The acid phosphate was valued at \$14 per ton, muriate of potash at \$50, and nitrate of soda at \$60. The extra cost of harvesting the increase of crops was placed at 10 cts. per bu. for cereals and \$1 per ton for hay. In the fertilizer tests at Wooster, Strongsville, Germantown, and Carpenter the use of phosphorus alone increased the yield of wheat from 4.85 to 8 bu. per acre, phosphorus and potassium from 6.2 to 9.19 bu., and phosphorus, potassium, and nitrogen from 8.77 to 16.2 bu. Based on all the crops of the rotation and taking into account the fertilizer cost and the expense of harvesting the increase, the average annual net value per acre of the increase from the use of phosphorus at the four points was \$2.87, from phosphorus and potassium, \$3.21; and from phosphorus, potassium, and nitrogen, \$2.60. The cost of the nitrogen in commercial forms did not justify its use in the growing of cereals. In these experiments manure gave a return of more than \$3 per ton without proper reinforcement with phosphorus, while in other experiments at the station a return of more than \$4 per ton has been secured.

The use of 1 ton of burnt lime or 2 tons of ground limestone per acre once in five years on the acid soil at Wooster increased the yield of wheat 2.11 bu. per acre as a 10-year average. The lime increased the value of all crops in rotation from \$6.17 to \$27.41 per acre, depending upon the fertilizer treatment. The average gain for lime per rotation was \$16.47 per acre. No treatment of the soil with fertilizers or manure rendered lime unnecessary.

Plowing 15 in. deep showed a gain of 0.43 bu. per acre over plowing 7.5 in. deep, and ordinary plowing with subsoiling showed a gain of 1.04 bu. of wheat over ordinary plowing alone. Neither deep plowing nor subsoiling proved profitable on the Wooster silt loam soil.

The results from broadcasting and drilling seed varied widely with the season. As an average of five seasons the gain for drilling was 3.8 bu. per acre. No difference in yield was found between drilling 1 in. and 2 in. deep, and a 3-in. depth showed but a slight decline. As an average of three tests with the same quantity of seed per acre, cross-drilling gave an average gain of 0.76 bu. of wheat per acre over drilling one way.

The results of making nine different seedings of wheat at intervals of one week, beginning September 1 and ending October 26, for a period of 14 years, were in favor of the seedings made September 21 and 22, with the seedings on September 28 and 29 standing next, and those of September 14 and 15 third. The results of experiments on the use of from 3 to 10 pk. of seed per acre and

[Vol. 35

extending over a period of 17 years with 10 different varieties showed that 8 pk. per acre proved most profitable, the use of 9 pk. standing second, and of 6 pk. third.

No important differences in yield were found in comparing heavy kernels of seed wheat with light kernels with such variations in weight as can be secured with the ordinary fanning mill. With hand-selected seed of pure line strains with variations in weight of 100 per cent or more, important increases in yield were obtained from the heavy kernels.

Of the varieties tested for 18 years the following, mentioned in decreasing order of yield, gave the best results: Dawson Golden Chaff, Nigger, Poole, Gipsy, Valley, Harvest King, Mealy, Gold Coin, Hickman, and Nixon. Dawson Golden Chaff, Mealy, and Gold Coin are reported as of inferior milling and baking quality. Variety tests conducted the last eight years and including five of the newer varieties not in the trial above mentioned showed Portage, Dawson Golden Chaff, Gold Coin, Gladden, Trumbull, Early Red Clawson, Harvest King, Red Wave, Hickman, and Poole, given in decreasing order, to have been the highest yielders. New varieties recommended to be seeded at the rate of 1 pk. per acre were found to require as heavy seeding as the old standard varieties.

In following the pure line method of selection decided differences in winter resistance, stiffness of straw, yield of grain, and breadmaking qualities are reported to have been found in the progeny of individual heads selected from ordinary varieties of wheat.

Some lessons from the wheat crop of 1915, C. E. Thorne (Mo. Bul. Ohio Sta., 1 (1916), No. 7, pp. 215-217).—Land growing wheat continuously without fertilization since 1894 yielded 10 bu. per acre in 1915, this being the largest yield in 12 years. The average production without fertilizers for the 22 years was raised to 7.5 bu. per acre. An annual dressing of 5 tons of barnyard manure per acre increased the yield to 23.8 bu. for 1915, and to 18 bu. for the 22 years, and 430 lbs. of complete fertilizer raised the yields to 22.6 bu. and 19.3 bu., respectively.

Wheat without fertilizer treatment grown in a 3-year rotation with corn and clover since 1898 yielded 17.3 bu. in 1915, and an average of 11.9 bu. for the 18 years. Where only the corn in this 3-year rotation received 8 tons of barnyard manure per acre, the yield of wheat in 1915 was 24 bu., the 18-year average being 20.7 bu. Manure applied at this rate but dusted with 40 lbs. of acid phosphate per ton gave a yield of 29.8 bu. per acre in 1915 and an average of 26.6 bu. for the 18 years.

In another 3-year rotation including clover and begun in 1894, wheat followed potatoes. In this test the unfertilized wheat yielded 33.7 bu. per acre in 1915, and averaged 26 bu. for the 21 years. Where both potatoes and wheat received 160 lbs. of acid phosphate on each crop, the wheat yield rose to 39 bu. in 1915 with an average of 35.4 bu. for the entire period. The addition to the acid phosphate of 100 lbs. of muriate of potash each for potatoes and wheat increased the yield to 40.7 bu. in 1915 and to 35.6 bu. for the entire period. A further addition of nitrate of soda, 80 lbs. per acre on potatoes and 160 lbs. on wheat, raised the wheat yield for 1915 to 43.2 bu. and for the 21 years to 37.7 bu. This was the same fertilizer application that raised the continuously grown wheat from 7.5 to 19.3 bu.

In a 5-year rotation with corn, oats, clover, and timothy, wheat without fertilizer treatment yielded 8.7 bu. per acre in 1915 and 10.6 bu. as the 22-year average on land that had never been limed, as compared with 15 bu. for 1915 and 11.7 bu. for the 22 years on land which had received a ton of quicklime per acre in 1903 and 2 tons of ground limestone 10 years later. Acid phosphate

at the rate of 160 lbs. per acre increased the yield for 1915 to 18.6 bu. on the unlimed land and to 20 bu, on the limed land. One hundred lbs. muriate of potash added to the acid phosphate produced a further increase of a bushel per acre for the 22 years in both cases, and the complete fertilizer in the same quantities given for the experiments above described increased the yield for 1915 to 33 bu, on both unlimed and limed land and to 27.5 bu, for the 22-year average, the nitrate of soda partly taking the place of lime.

In addition to these plat experiments, a 40-acre field at the station has grown 10 acres of wheat annually for 22 years in a 4-year rotation with corn, oats, and clover. The first 10 years the wheat land was top-dressed before seeding with about 10 tons of barnyard manure per acre and the 10-year average yield was 20 bu. Then the manure was reinforced with about 40 lbs. of acid phosphate per ton and spread on clover sod which was plowed under for corn. The corn received a dressing of about 1.5 tons of limestone per acre and the wheat received 350 lbs. per acre of a fertilizer made up of steamed bone meal, acid phosphate, and muriate of potash with 50 lbs. of nitrate of soda added in April if the growth was not too rank. The wheat yield on this field for 1915 was nearly 36 bu., and the average yield for the past 10 years 34 bu. per acre.

#### HORTICULTURE.

[Report of horticultural investigations], W. H. LAWRENCE and S. B. Johnson (*Arizona Sta. Rpt. 1915*, pp. 539-552).—A progress report on various lines of work for the year.

Studies with processed fabrics prepared for use in protecting citrus trees during injurious low temperatures (E. S. R., 33, p. 48) were continued, and observations reported as to semitransparency, air-tightness of covers, radiation of heat from covers, distribution of heat, and changes of temperature due to wind currents under covers.

The results are given of fruit-thinning experiments conducted with a number of young date trees. These results, together with observations and study of the influence of thinning fruit on old trees, led to the following conclusions:

"The date palm is a plant having a natural method of thinning fruit. The fruit begins to drop shortly after pollination takes place and continues long after the reduction to one of the three carpels occurring in each floral cup, sometimes continuing into the harvest period. Trees not bearing a maximum crop will mature fruit to size and quality with little or no change in earliness of ripening. Natural methods of thinning fruit early in the season have a greater tendency to increase the size of the berry, in proportion to the number in the bunch, than is induced by artificial removal of a number of berries later in the season following natural thinning. Artificial thinning may be done to advantage only after the bearing capacity of a tree has been determined.

"Thinning may be done most effectively and quickly by the removal of an entire fruiting branch. This method not only increases the weight of the berry but of the entire bunch, including the brush. Thinning may be done profitably when the tree is carrying in excess of a maximum load. Under these conditions bunches with one-half the spikes removed begin to ripen their fruit earlier than the nonpruned bunches, which come second in order, while those with one-half of each spike removed mature the fruit more slowly. In general, fruit of inferior size occurs on the slender-stemmed bunches, bearing weak branches."

In a cultural test of winter radishes the white varieties gave the best results. For rate of maturity and length of time the roots continue to grow and remain edible, White Icicle was the first choice.

Some data are given on the range of soil temperatures during the season, and the importance of using such records to determine dates for planting, methods of irrigation, and rate of growth of vegetables until edible maturity is pointed out.

Observations and data secured from experiments in the station's European and American grape vineyard during the fruiting seasons of 1914 and 1915 are here summarized under the general headings of bearing habits of the plant, systems of pruning, yields per season, date of blooming, weight of average size bunches, date of picking, decrease in size of berries, decrease in number of berries per ounce, comparison of yields for separate pickings from all hills of each variety, and yield of fruit.

In an olive orchard planted late in March and early in April, 1914, it was noticed early in May that many of the trees were discolored. Near the middle of the month a considerable increase in the cankered areas was noted, but all attempts to isolate an organism gave negative results. A further study showed that the trouble made its appearance on the trees first on the south or southwest side and near the ground.

Some experimental work was carried on in which plantings were made under various conditions, and it was found that sun scald of newly planted olive trees occurs under certain conditions. Small, weak-growing trees usually died before sun scalding took place, while large growing stems were not affected. Shading the trees did not prevent sun scald, while flooding with irrigation water and the use of hot soil as a surface mulch, with subirrigation, favored the scalding. Medium-sized trees that gave up their water slowly were found most susceptible to the injury. Scalding took place only during periods of intense heat, and under average field conditions is limited to the area just above the ground. Fall, winter, or early spring planting is deemed more desirable than late spring planting, and trees should be headed back at the time of planting in order to reduce the evaporation as much as possible.

Report of the horticultural department, J. E. Higgins (*Hawaii Sta. Rpt.* 1915, pp. 20-27, pls. 2).—The work of the department was continued along lines previously noted (E. S. R., 32, p. 741).

The station is cooperating in experiments in Florida and in California with the view of extending the culture of litchi (*Litchi chinensis*). Some successful experiments in transporting these short-lived seeds under refrigeration from Honolulu to San Francisco and thence by ordinary express and by mail in moist sphagnum moss to Washington, D. C., and to various localities in California are noted. All of this seed germinated well, thus indicating that litchi seeds may be transported where refrigeration for fruit is available.

In the work with mangoes some preliminary studies have been made on the flowers of certain varieties and on methods of pollination. Several mango seedlings less than nine months old, which had been grafted by inarching, were found to be producing flower clusters above the point of union, and in most cases the scion also was flowering. The mango tree ordinarily does not flower until it is from five to six years old. No cause is ascribed for these phenomena, except the grafting. An instance of bud mutation is reported in which a single branch of one of the trees bearing green fruit produced a pink fruit rather smaller in size than the regular type but otherwise resembling the variety. Bark grafting the mango, which has previously been successfully applied by the Porto Rico Experiment Station, has proved to be well adapted under Hawaiian conditions to the work of top grafting established trees. The process is here described.

In the work with avocados the Macdonald, the parent tree of many of the round, hard-shelled winter seedlings, has attracted some attention by its remarkable keeping qualities. The fruits were kept in the horticultural laboratory for 16 days without any refrigeration, being in a perfect state of preservation at the end of this time.

In the work of propagating the avocado, scion budding has given satisfactory results. The scions are inserted in a T-shaped incision similar to that made for shield budding, only much larger. After being tied in place the budded scion is waxed with a firm grafting wax which will not run when heated by the sun. This method is considered to be advantageous as a means of propagating from old bearing trees which frequently do not produce good bud wood unless severely cut back. It may also be used to work branches of considerable size. Observations of apparently multiple-stemmed seedling avocados showed that such seedlings have a single central stem, the other stems arising from buds on this stem beneath the surface of the ground and in many cases within the seed.

The work of breeding papayas was resumed along lines previously noted. A number of crosses and close pollinations have been made to secure information on questions arising in earlier work.

In the citrus orchard many varieties are now in bearing and making a satisfactory growth. Practically all of these varieties have been introduced as bud wood and worked upon home-grown stocks.

In view of the claim by some manufacturers that a blend of the oil of kukui (Aleurites moluccana) and of the China wood oil (A. fordii) is preferable to either one, some work was undertaken by V. S. Holt in hybridizing these species with the idea that the new forms might combine the desired characters in a way superior to either of the parents. A number of fruits from these cross pollinations have been secured.

Brief notes are given on the station's distribution of seeds and plants and extension work in horticulture.

A variety test of tomatoes, C. E. Myers (*Pennsylvania Sta. Rpt. 1914, pp. 461-492*).—In continuation of a previous report (E. S. R., 34, p. 146) tabular data are given on a test of different strains of a number of varieties of tomatoes. With a few exceptions each variety recorded has been tested for three years. The varieties are classified according to their period of maturity, described, and discussed with reference to their quality and commercial importance.

Influence of dynamiting on soils, W. R. White (Pennsylvania Sta. Rpt. 1914, pp. 445-457).—In continuation of a previous report (E. S. R., 34, p. 125) the second year's results are given from those dynamiting experiments, which were conducted in orchards. Although these results are not considered conclusive thus far, they indicate, as in the previous year, that the profitable application of dynamite as a soil improver is limited. In these experiments no important gains have as yet been derived from its use either with newly-planted apple trees or with mature trees.

Irrigation, R. W. Allen (*Oregon Sta.*, *Rpt. Hood River Sta.*, 1915, pp. 24-26. fig. 1).—Practical suggestions are given for irrigating orchards, both where cover crops are used and where clean tillage is practiced.

Cover crops, C. I. Lewis and R. W. Allen (Oregon Sta., Rpt. Hood River Sta., 1915, p. 29).—Notes are given of a test of various cover crops on a number of distinct soil types in the fall of 1914. The crops tested include field peas. horse bean, crimson clover, hairy vetch, spring or common vetch, woolly-podded vetch, purple vetch, and bitter vetch.

As a result of the severe winter only the crimson clover and hairy vetch survived and made satisfactory growth to be of value for green manuring. The

authors point out, however, that field peas may be grown in the spring for green manure as well as for forage or for grain. Crimson clover reaches the proper size for use as green manure too late in the spring to be of very great value. Of the newer vetches—woolly-podded, bitter, and purple—the first two are promising but do not appear to be much more hardy than spring vetch. Spring vetch succeeds well in ordinary years and, unlike hairy vetch, the seed is cheap and easily obtained, hence it will of necessity be most generally used.

Results from experiments on cultural methods, cover crops, and fertilization in apple orchards, J. P. Stewart (*Pennsylvania Sta. Rpt. 1914, pp. 423-438*).—In continuation of a previous report on this subject (E. S. R., 34, p. 148) the author reviews some of the more practical results secured from certain of the orchard fertilizer experiments. The principal results from the other orchard experiments of the station are appended in tabular form.

The results secured from cultural methods in the younger orchards are, in general, not materially different from those previously given. Some of the recent results in the more mature orchards, however, conflict with previous results, the tillage and cover crop plats giving the best yield in some cases and mulched trees the best yield in other cases. In the latter cases definite amounts of plant food have also been added to both the cultural plats and the mulched plats. Tree growth has continued to be decidedly greater throughout the experiment for the tillage and cover crop treatment.

Observations on the experiments as a whole appear to demonstrate the feasibility of obtaining practically annual crops from such supposedly refractory biennial bearers as the Baldwin, York Imperial, Spy, and Tompkins King, provided the conditions are made right. The results also indicate that annual tillage should be done with double-action disks or cutaways or their equivalent in preference to regular plows, wherever the soil conditions will permit.

In one experiment, here noted, the influence of fertilization surpassed that of cultural methods as regards yield. The application of nitrogen with phosphate to sod or of manure to sod gave strikingly greater yields than sod mulch or tillage and cover crop methods of culture. Phosphate with potash applied to sod gave a material gain over sod alone but was less effective in influencing the yield than sod mulch or tillage and cover crop.

From the results secured in this work to date a general fertilizer formula carrying about 30 lbs. of actual nitrogen, 50 lbs. of actual phosphoric acid, and from 25 to 50 lbs. of actual potash, applied at the rate of 500 lbs. per acre to bearing trees, is recommended. Attention is called, however, to the need of adjusting the fertilizer to individual orchards.

Intercrops for apple orchards, J. P. Stewart (*Pennsylvania Sta. Rpt. 1914*, pp. 439-445).—In this paper the author calls attention to the value of intercrops in reducing the cost of young orchards and gives concise directions for growing the various intercrops in the orchards.

The influence of nitrogen upon the vigor and production of devitalized apple trees, C. I. Lewis and R. W. Allen (*Oregon Sta.*, *Rpt. Hood River Sta.*, 1915, pp. 5-19, pl. 1, figs. 4).—Further results are given of some of the station's orchard fertilizer experiments in which the ingredients are being applied both in the dry form and in solution (E. S. R., 35, p. 235).

The present report deals specifically with the effects of nitrogen, which is the only element that has given results. In the previous year's work beneficial results were secured by spraying trees with a solution of nitrate of soda and caustic soda, thus confirming the results reported by Ballard and Volck (E. S. R., 30, p. 640). Subsequent experiments, however, lead the authors to conclude that the real reason why better results were secured from spraying nitrate of soda than applying it in the dry form was due to the

fact that the nitrogen sprayed on the trees was dissolved and reached the roots, whereas the nitrates spread on the ground were added in May when the ground was dry, hence did not dissolve and reach the roots. In order to secure benefit from the nitrates they should be applied during the early part of March when the ground is sufficiently moist to dissolve them and also before the trees come into bloom. Nitrogen applied at this time has been found to cause a larger percentage of set of fruit in April, an important change in the character of the foliage, and a stimulation of the wood growth.

The experiments indicate that the stimulating effect of nitrate of soda is more lasting in its effects than formerly believed and that its benefits will extend over into the second season and perhaps longer. The best method of applying nitrate of soda to orchards is to spread the dry crystals broadcast on the ground under the trees and harrowing soon after applying. Six lbs. of nitrate of soda, equal to about 1 lb. of actual nitrogen, applied to a mature bearing tree is believed to be ample to restore seriously weakened trees to a normal condition. This amount should be reduced one-half the second year, the station's experiments showing that a full pound of nitrogen applied the second year produced too much wood growth and too much fruit that was undercolored and oversized. The cost of furnishing the required nitrogen at the rate recommended was \$15 an acre.

The above amounts of fertilizer are recommended for use only on trees which are in a somewhat run down condition as indicated by thin foliage, weak wood growth, small fruit, and the presence of certain physiological troubles, such as "fruit pit," little leaf, die-back, etc.

Further experiments are to be conducted to confirm these conclusions as a whole.

The authors point out that nitrate of soda does not exert much influence on the soil, and therefore in order to improve the physical condition of the soil in many orchards it is necessary to add organic matter. During the last two years those orchards which have used clover and alfalfa in the presence of sufficient moisture have shown a strong improvement. The use of these leguminous crops should be dispensed with for a while and systematic clean culture practiced when signs of over stimulation appear.

Condition of root system of apple trees in the Hood River district, R. W. Allen (Oregon Sta., Rpt. Hood River Sta., 1915, pp. 20-24, figs. 2).—The results are given of a preliminary investigation started in 1913 to determine in a general way the condition of the root system of apple trees in orchards varying in age and under different cultural treatment.

In the orchards examined many of the fibrous roots of the trees were dead, this condition being worse in old orchards kept under clean cultivation and without irrigation. Sod culture without irrigation was very similar in result to that of continuous clean culture, but the conditions, as a whole, were worse where shallow implements of tillage had been used. Sod culture in which clover had been grown with irrigation showed the soil and roots of trees to be in very good condition.

"Fruit pit" was found to be worse under the worst conditions of the soil and upon trees having root systems in the most critical condition. In less serious conditions of soil the roots of "pit" trees were either normal in vigor or nearly so. Winter injury appeared to be most prevalent on soils of poor condition, but no relation was found to exist between the seriousness of the trouble and the condition of the roots of the trees. The investigation as a whole strongly indicates that the weak and yellow condition of the trees, much of

the fruit pit, and winter injury now so prevalent in the orchards are due to drought and improper fertilization.

Winter injury to apple tree roots (Wisconsin Sta. Bul. 268 (1916), pp. 15, 16).—Observations made by the horticultural department on root killing of apple trees show that when there is a blanket of snow upon the ground even excessive variations in air temperatures do not cause much fluctuation in soil temperatures; hence cover crops which hold the snow aid in preventing winter-killing.

The results of one year's work further indicate that the roots arising from scions of hardy varieties of apples can withstand greater cold than roots of equal size developing from the stock. Considerable difference existed in the ability of scion roots of different varieties to resist low temperatures. Scion roots of the Wealthy, for instance, are much hardier than those of the Northwestern Greening. J. G. Moore of the station has observed that ordinarily no scion roots are produced the first year. Usually those produced the second season are small, and less than 50 per cent of the 3-year-old apple stock had any scion root development. Consequently too much reliance can not be placed upon the development of scion roots by young trees as a factor to enable the trees to resist winter conditions.

Ripening of growing parts of orchard trees and shrubbery, A. D. Selby (Mo. Bul. Ohio Sta., 1 (1916), No. 7, pp. 206-208, fig. 1).—Attention is called to the danger of the unripened condition of orchard trees and shrubbery due to various causes, with suggestions for the ripening of the wood so that winter injury does not follow. Among the causes of the unripened condition are heavy manuring, excessive pruning, late cultivation, defoliation by leaf spot and other fungi, etc.

Suggested grades for peaches, M. A. Blake and C. H. Connors (New Jersey Stas. Circ. 58 (1916). pp. 8, figs. 4).—In continuation of suggestions relative to grading peaches given in a previous bulletin of the station (E. S. R., 34, p. 639), the experience gained during 1915 is included in the present circular. A descriptive outline for standard varieties is given showing the amount of color these varieties should have to be classed as "fancy" fruit.

Horticultural observations in Porto Rico, Cuba, and Florida in relation to the horticulture of Hawaii, J. E. H. LINS (Hawaii Sta. Rpt. 1915, pp. 58-73, pls. 3).—A comparative study of the fruit industries in Porto Rico, Cuba, and Florida, with special reference to similar industries in Hawaii. The fruits considered include the pineapple, citrus fruits, the avocado, and the mango. Information is given relative to the extent of the industries, cultural methods, principal diseases and insects, and marketing.

#### FORESTRY.

Third biennial report of the state forester, 1914, J. C. VAN HOOK (Bien. Rpt. State Forester Mont., 3 (1913-14), pp. 35, pl. 1).—A brief account is given of the lumber industry in Montana, together with descriptions of the commercial woods of the State, methods of administering the state forests, and the work of forest protection.

Fifth annual report of the state forester, F. A. ELLIOTT (Ann. Rpt. State Forester Oreg., 5 (1915), pp. 22).—A progress report on the work of the State Board of Forestry, with special reference to the work of forest protection.

Report of the state fire warden, C. P. Wilber (Ann. Rpt. Dept. Conserv and Develop., N. J., 1915, pp. 47-77, pls. 3).—The report of the 1915 season relative to the work of forest fire protection in New Jersey.

Report on forest operations in Switzerland (Rap. Dépt. Suisse Int., 1915, pp. 1-10).—A report on the administration and management of the state, community, and private forests in Switzerland, including tabular data showing yields in major and minor products, revenues, expenditures, etc., as well as operations in forest extension.

Report on the forest administration in Burma for the year 1914–15, C. G. Rogers (*Rpt. Forest Admin. Burma*, 1914–15, pp. VI+109).—The usual progress report relative to the administration and management of the state forests in Burma, including a financial statement for the year. The important data relative to alterations in forest areas, forest surveys, miscellaneous work, revenues, expenditures, etc., are appended in tabular form.

Annual report on the forest administration in Ajmer-Merwara for the year 1914-15, HUKAM CHAND (Ann. Rpt. Forest Admin. Ajmer-Merwara, 1914-15, pp. 4+28).—A report similar to the above relative to the administration of the state forests in Ajmer-Merwara during 1914-15.

Report on forest administration in the Andamans for 1914–15, J. W. A. GRIEVE (*Rpt. Forest Admin. Andamans, 1914–15, pp. 4+38*).—A report similar to the above relative to the administration of the state forests of the Andamans for the year 1914–15.

Administration report of the forest circles in the Bombay Presidency, including Sind, for the year 1914-15 (Admin. Rpt. Forest Circles Bombay, 1914-15, pp. II+180+4).—A report similar to the above relative to the administration of the state forests in the Northern, Central, and Southern Circles of the Bombay Presidency, and of Sind.

Progress report of forest administration in Coorg for 1914-15, H. Tireman (Rpt. Forest Admin. Coorg, 1914-15, pp. 3+13+13).—A report similar to the above relative to the administration of the state forests in Coorg for the year 1914-15.

Seeding and planting, J. W. Toumer (New York: John Wiley & Sons, 1916, pp. XXXVI+455, figs. 140).—A manual of information on seeding and planting in forest practice, with special reference to conditions in the United States. In the preparation of the work the forestry literature of Europe has been freely drawn upon for the principles underlying these practices.

In part 1, under the general heading of silvical basis for seeding and planting, consideration is given to definitions and generalities, the choice of species in artificial regeneration, the principles which determine spacing, and the principles which govern the composition of the stand. Part 2 takes up the artificial formation of woods, consideration being given to forest tree seed and seed collecting, the protection of seeding and planting sites, preliminary treatment of seeding and planting sites, establishing forests by direct seeding, the forest nursery, and establishing forests by planting.

The testing of pine seeds, A. GRISCH (Landw. Jahrb. Schweiz, 30 (1916), No. 2, pp. 210-224, figs. 2).—A report on the knowledge of the count and weight methods of testing pine seeds.

Observations on some oaks with persistent foliage, G. Donati (Ann. Bot. [Rome], 13 (1915), No. 2, pp. 157-168, figs. 13).—The author here presents a comparative study of the leaf structure of Quercus ilex, Q. suber, Q. occidentalis, and Q. coccifera.

A list of the recognized woods of British Guiana (New York: The British Guiana Consolidated Co., Ltd. [1916], pp. 18, flgs. 6).—A descriptive list of British Guiana woods compiled from various government reports. Information is given relative to the specific gravity of the wood, appearance, physical texture, and uses.

Rubber (Trans. 3. Internat. Cong. Trop. Agr. 1914, vol. 1, pp. 594-728, fig. 1).—This includes abstracts of the following papers on rubber, including reports of discussions, at the Third International Congress of Tropical Agriculture, London, July, 1914: The Cultivation of Hevea brasiliensis in Uganda, by S. Simpson (pp. 594, 595); Diseases of Hevea in Ceylon, by T. Petch (pp. 596-607); On Some Animal Pests of the Hevea Rubber Tree, by E. E. Green (pp. 608-636); Termes gestroi as a Pest of the Para Rubber Tree, by H. C. Pratt (pp. 637-640); The Principles of Hevea Tapping, as Determined by Experiment, by T. Petch (pp. 641-651); The Preparation of Plantation Para Rubber, by B. J. Eaton (pp. 652-678); Spottings in Plantation Rubber Due to Fungi, by A. Sharples (pp. 679-687); Ceara Rubber Cultivation and Manufacture in Southern India, by R. D. Anstead (pp. 688-696); The Cultivation of Manihot glaziovii in Uganda, by S. Simpson (pp. 697, 698); Increase in Yield from Funtumia elastica in Belgian Kongo by the Sparano Method, by A. Gisseleire (pp. 699-701); The Methods of Tapping Cultivated Castilla Trees, and the Yield of Rubber Therefrom, by P. Carmody (pp. 702, 703); The Methods of Tapping Castilla Rubber Trees in Mexico, and the Yield of Rubber Which the Trees Furnish, by A. Russan (pp. 704-712); Rubber Culture in the German Colonies, by F. Frank (pp. 713-719); Necessity to the Rubber Industry of the Exact Laboratory Determination of the Respective Values of Rubber, by Lamy-Torrilhon (pp. 720-722); and Contribution to the Knowledge of the Mechanism of Coagulation in Certain Rubber-Yielding Species, by F. Heim and R. Marquis (pp. 723-728).

A comparison of the Brazilian and plantation methods of preparing Para rubber, G. S. Whitby (Jour. Soc. Chem. Indus., 35 (1916), No. 9, pp. 493-502).—In this paper the author describes a comparative test of the methods of preparing plantation rubber in the eastern Tropics and the wild rubber of Brazil.

The rubber industry of the Amazon and how its supremacy can be maintained, J. F. Woodroffe and H. H. Smith (London: John Bale, Sons & Danielsson, Ltd., 1915, pp. XLVIII+435, pls. 42, figs. 4).—This work comprises a study of the rubber industry and the labor, social, and various economic conditions in Brazil, with special reference to pointing out ways and means for the future development and maintenance of the rubber industry in connection with the general development and settlement of the Amazon region.

## DISEASES OF PLANTS.

Plant pathology problems (Wisconsin Sta. Bul. 268 (1916), pp. 18-25, figs. 6).—Brief accounts are given of the various investigations in plant diseases that are being carried on by the department of plant pathology. This work includes a study of leaf roll and similar troubles of potato, seed disinfection for the control of scab and Rhizoctonia, studies of nonparasitic diseases of potato such as black heart, a study of alfalfa diseases, and the control of barley diseases, cabbage yellows, and cucumber diseases.

For the control of barley diseases, A. G. Johnson has investigated the effect of planting at intervals of two weeks throughout the season with the result that the early plantings in most cases developed more disease than the midsummer plantings. Attempts were made to control the stripe and blotch of barley by treating the seed with hot water, solutions of copper sulphate, copper sulphate and salt, corrosive sublimate, and formalin, with the result that warm solutions of formalin proved to be the most satisfactory treatment. Soaking seed for three hours in a solution of 1 pint formalin to 30 gal. water at a temperature of 68° F. gave satisfactory control not only of the stripe disease but also of the loose and covered smuts.

The work begun by the department of plant pathology some years ago in developing resistant strains of cabbage has resulted in the establishment of such strains and the production of a considerable amount of seed for testing in 1916. Trials made in different regions indicate that the disease-resistant quality is maintained even in widely different localities. In connection with this disease, J. C. Gilman has observed that the growth of the parasitic organism causing it is greatly increased at temperatures above 64°. This, it is believed, will explain why the disease is so much more serious in some seasons than in others, and also indicates that it will not be so severe in the northern as in the southern parts of the State.

Some observations on pea blight were continued, and the former recommendations of careful preparation of seed bed and attention to drainage are repeated. For the disposal of the refuse vines the use of silos is suggested.

Some investigations had been begun on cucumber diseases, of which wilt, angular leaf spot, anthracnose, and scab are said to be due to definite parasites, while a fifth, white pickle or cucumber mosaic disease, is not known to be due to any organism. These five diseases are said to be more or less serious in Wisconsin. The white pickle or cucumber mosaic disease is characterized by irregular malformed fruits which are usually worthless for pickling purposes. The trouble is considered transmissible, but as yet no parasite has been discovered. Similar conditions have been found to obtain with squash and watermelon, from which the disease may be transferred to the cucumber.

Studies on the crown gall of plants. Its relation to human cancer, E. F. SMITH (Jour. Cancer Research, 1 (1916), No. 2, pp. 231-309, figs. 92).—The present paper, which reviews certain of the essential features of crown gall, especially as they bear upon the general problems of cancer, also contains a number of new observations which are considered to bring this vegetative growth into relations with the group of tumors described as embryomata.

The author calls attention to the growth without function exhibited by the crown gall tumors, the cell itself being properly regarded as parasitic only in the sense that it is urged on by a schizomycete, Bacterium tumefaciens, and to the embryonic character of the proliferating tumor cells. Attention is called also to the atypical arrangement of the tissues, to their loss of polarity, and to the slight differentiation of the cells accompanying their increase in vegetative vigor. The neoplastic character of the growths is emphasized by the noncapsulate marginal growth, the imperfect vascularization, the early central necrosis, the existence of intrusive strands, and the occurrence of daughter tumors, which reproduce the original tumor. The same micro-organism is capable of producing by inoculation different types of tumors varying in structure according to the type of tissue invaded, the most complex type containing, along with blastomous elements, a jumbled and more or less fused mass of embryonic organs and fragments of organs comparable, if not equivalent, to the foetal organs occurring in the atypical animal teratoids.

The distribution of black rust in Norway, E. Henning (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 107 (1915), pp. 16; K. Landtbr. Akad. Handl. och Tidskr., 54 (1915), No. 2, pp. 122-135; abs. in Bot. Centbl., 128 (1915), No. 18, pp. 495, 496).—It is thought that the barberry was introduced into Scandinavia at least as early as the beginning of the seventeenth century, and black rust of wheat (Puccinia graminis) not later than the eighteenth, and possibly in the seventeenth, century. Since this time the barberry has been used as alternate host, both barberry and fungus being more successful in the middle and southern portions than in the north, where the rust has little economic importance.

Diseases of garden vegetables in Switzerland, E. Mayor (Rameau Sapin, 48 (1915), pp. 39, 40, 44-47; 49 (1915), pp. 7, 8, 12-15; abs. in Bot. Centbl., 129 (1915), No. 1, p. 6).—A brief review is given of diseases of garden vegetables, particularly in the Canton of Neuchâtel, also of corresponding control measures.

The physiology of Phoma betæ, R. Schander and W. Fischer (Landw. Jahrb., 48 (1915), No. 5, pp. 717-738).—Reports of previous investigations by one of the authors (E. S. R., 28, p. 628; 33, p. 53) are followed up with a detailed account of studies on *P. betæ* as affected by modifications of the nutritive medium, by temperature, and by poisons as employed in sprays.

Hot water does not seem to be practically protective against this fungus. Among the more satisfactory chemical sprays mentioned are corrosive sublimate and a few proprietary preparations.

Club root of cabbage, C. Hammarlund (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 106 (1915), pp. 14, figs. 7; K. Landtbr. Akad. Handl. och Tidskr., 54 (1915), No. 2, pp. 110-121, figs. 7).—Experiments on control of cruciferous club root (Plasmodiophora brassicæ) gave results which were most favorable to formalin in regard to the expense, which is only one-third that of carbon bisulphid, and in regard to its harmlessness as compared with lime in large percentages. It was proved that the disease is spread by feeding the diseased plants to cattle, which does not destroy the organism, though its dispersal in this way may be avoided by thoroughly cooking the plants.

Glæosporium caulivorum injuring red clover in Hungary, D. Hegyi (Mezögazdasági Szemle, 33 (1915), No. 2, pp. 55-58; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 4, p. 637).—In different portions of Hungary, but particularly those along the right bank of the Danube, great injury was done in 1914 to red clover by G. caulivorum. As the fungus is thought to be carried by the seeds, it is recommended that these be soaked in 1 per cent solution of copper sulphate before planting.

Transmission and control of bacterial wilt of cucurbits, F. V. RAND and ELLA M. A. ENLOWS (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 11, pp. 417-434, pls. 2, figs. 3).—The authors have made a study of insect transmission of the bacterial wilt of cucurbits. Experiments, as far as completed, indicate that cucumber beetles (Diabrotica spp.) are the most important, if not the only, carriers of the wilt organism (Bacillus tracheiphilus), and that at least one species (D. vittata) is capable of carrying the wilt over winter and infecting the spring plantings of cucumbers.

In spraying experiments carried on in 1915, the wilt was effectively controlled by a spray consisting of a combination of Bordeaux mixture and arsenate of lead. Plats sprayed with either alone showed less wilt than unsprayed plats, but the control was not so complete as when the two were used together. Inasmuch as it has been proved that insects are the carriers of the disease, insect control becomes necessary for preventing the wilt. This phase of the work is to be given further study in cooperation with the Bureau of Entomology of this Department.

Bacteriosis of cucumber in Italy, G. B. Traverso (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 5, pp. 456-460).—A serious bacterial disease of cucumbers is described as having appeared in May, 1914, following a severe outbreak of Glæosporium lagenarium in 1913. The disease appears on the adult leaves and the fruits while the roots and young shoots are still normal. Bordeaux mixture, if applied to the plants when very young, is thought to have some protective value.

Leaf rust of cucumber, P. Sprenger (Mitt. K. K. Gartenbau Gesell. Steiermark, 41 (1915), No. 1, pp. 4, 5; abs. in Bot. Centbl., 128 (1915), No. 15, p.

.115).—Against Corynespora melonis, causing a spread of leaf rust in Germany, a 1 per cent Bordeaux spray for the young plants is recommended as preventive. Seed should be kept for 1.5 hours in 0.5 per cent formalin before sowing. After the outbreak has occurred, it is necessary to destroy completely all plants with their fruits, or to remove them to some unused portion of the field which can be left uncultivated for several years.

Ginseng diseases and their control, H. H. WHETZEL, J. ROSENBAUM, J. W. BRANN, and J. A. McCLINTOCK (U. S. Dept. Agr., Farmers' Bul. 736 (1916), pp. 23, figs.26).—This describes in a popular way the diseases of ginseng and their control, technical descriptions of the different diseases having been previously noted (E. S. R., 27, p. 649).

The neck rot of white onions, J. G. Humbert (Mo. Bul. Ohio Sta., 1 (1916), No. 6, pp. 176–180, fig. 1).—Results from an investigation on the neck rot of white onions, due to Sclerotium cepivorum, are given. This disease is said to have been the cause of heavy loss in stored onions, and experiments for control, including sanitation methods and fumigation with formaldehyde gas, have been carried on with some success. Dump heaps of rotting onions should not be permitted, and crates and storage houses should be disinfected if the new crop is to be kept free from disease.

This disease has been confused with smut, but this attacks the growing onions, while the neck rot is apparently a trouble which destroys the mature onions in storage.

Potato dry spot in Java, A. RANT (Teysmannia, 26 (1915), No. 5, pp. 285-287, pls. 2).—A disease of potato leaves is described which is thought to be identical with early potato blight due to Alternaria solani.

Root rot of tobacco (Wisconsin Sta. Bul. 268 (1916), pp. 17, 18, figs. 2).—A brief account is given of the work of J. Johnson on the rooot rot of tobacco, due to Thielavia basicola, and methods for its control. Since certain strains of tobacco have been found to differ widely in susceptibility to the disease, an attempt is being made to develop a resistant type which will be of high quality and also able to grow on worn-out tobacco fields. Until such a type is secured, it is recommended that growers sterilize the soil of seed beds or plant on soil that has not grown tobacco in recent years.

Bacterial rot of tomato, V. Peglion (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), II, No. 3, pp. 157-160).—A rot of tomato appearing in May, 1914, was reproduced in characteristic form by inoculation with a bacterium isolated from the decayed fruits. The organism appears to lose quickly much of its virulence in artificial substrata.

Root rot of fruit trees, J. J. THORNBER (Arizona Sta. Rpt. 1915, p. 530).—In continuation of work by McCallum, discontinued in 1910, the author made an examination of orchards where root rot was causing serious loss. It is considered that more than one fungus is responsible for root rot, and in the absence of definite information, no positive methods for control can be given. This investigation is to be continued.

Study of Coniothyrium pirina, Phyllosticta pirina, and C. tirolense, ELISA MUTTO and G. POLLACCI (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), II, No. 1, pp. 40-42).—Evidence is adduced to show that the fungus denominated C. pirina by Sheldon (E. S. R., 19, p. 249) is, as that author suspected, not identical with P. pirina but that it has characters corresponding precisely to those of C. tirolense.

Tree crickets as carriers of Leptosphæria coniothyrium and other fungi, W. O. GLOYER and B. B. FULTON (New York State Sta. Tech. Bul. 50 (1916), pp. 3-22, pls. 4).—The authors propose the name tree-cricket canker for a disease

of apple branches, in which areas of dead bark infested with Coniothyrium fuckelii surround oviposition punctures of tree crickets.

The constant association of this fungus with such cankers led to an investigation of tree crickets as its carriers. It was found that tree crickets may carry the fungus from raspberries to apple trees and infect them, and also that they may carry the spores of these and other fungi in the digestive tract as well as on the outside of their bodies. Feeding experiments showed that the spores of Ustilago zew, Coprinus micaceus, Coniothyrium fuckelii, Nummularia discreta, and Sphwropsis malorum passed through the digestive tract of tree crickets without loss of viability.

Typical cankers resulted when tree crickets fed on *C. fuckelii* were allowed to oviposit on apple branches. The percentage of cankers formed about oviposition punctures was considerably greater when the crickets were fed with *C. fuckelii* from raspberry canes than when they were fed with pure cultures of the fungus isolated from apple branches. The oviposition punctures of *Ecanthus niveus* gave a higher percentage of infection than those of *E. angustipennis*, and for both species the percentage of infection was considerably higher when the punctures were covered with grafting wax than when left uncovered. Typical cankers were also produced by inserting pellets of tree-cricket excrement into punctures made in apple branches and covering them with grafting wax.

Clean cultivation and the use of arsenical sprays are suggested as remedial measures for the control of tree crickets.

Collar blight of apple trees, C. R. Orton and J. F. Adams (*Pennsylvania Sta. Rpt. 1914, pp. 152–160, pls. 3*).—This is an account of an investigation of collar blight of apple trees, due to the organism *Bacillus amylovorus*, a more extended report of which has been noted (E. S. R., 34, p. 247).

The spraying experiments of 1915 in the Hood River Valley for the control of apple scab, J. R. Winston and L. Childs (*Oregon Sta., Rpt. Hood River Sta. 1915, pp. 30–46, figs. 5*).—A report is given of experiments carried on in the Hood River Valley for the control of apple scab which, in the last few years, has become a very serious pest in this region. In 1914, cooperative experiments were carried on with a number of growers, and in 1915 work was continued on three orchards in which Winesap and Newtown apple trees were sprayed with various fungicides to test their efficiency. Bordeaux mixture, soluble sulphur, barium tetrasulphid, atomic sulphur, and iron sulphid were tested in comparison with lime-sulphur solution. In addition, the time of application was studied, particular attention being paid to the delayed dormant application, in which trees were sprayed with a rather strong lime-sulphur solution just as the leaves were beginning to show from the winter buds.

The delayed dormant application proved valuable in some instances, increasing by about 12 per cent the sound fruit. Lime-sulphur proved the most efficient fungicide tested, the addition of atomic sulphur in one instance apparently decreasing its fungicidal properties, and the addition of iron sulphid apparently decreasing the fungicidal properties and slightly increasing the injurious qualities. Bordeaux mixture caused serious russeting of the fruit. The barium tetrasulphid used in strengths recommended by the manufacturers did not prove so efficient as lime-sulphur in controlling scab. Atomic sulphur proved a very poor substitute for lime-sulphur in the later applications. Soluble sulphur was less efficient and decidedly more injurious than lime-sulphur, but it was more efficient than atomic sulphur, iron sulphid, or barium tetrasulphid.

Based on two years' work, the authors claim that by thorough application of fungicides apple scab may be controlled in the Hood River Valley, even in years favorable to epidemics of the disease. A tentative spray calendar for

1916 is given for the control of scab and mildew, or of scab alone, in the Hood River Valley. This includes the use of lime-sulphur as a delayed dormant spray, followed by a more dilute lime-sulphur just as the petals are beginning to open, with a third spraying immediately after the petals have fallen. In the third spraying the authors recommend the use of atomic sulphur if the weather is clear and warm, or lime-sulphur with atomic sulphur added if the weather is cool and rainy. Two other applications are recommended, depending upon conditions in the orchards. In the first application, for the control of purple aphis nicotin may be used, and in the third and fifth lead arsenate may be added to the fungicide as a protection against codling moth injury.

Six years of experimental apple spraying at Highmoor Farm, W. J. Morse (Maine Sta. Bul. 249 (1916), pp. 81-96).—In previous publications (E. S. R., 33, p. 648) accounts have been given of the results obtained from spraying experiments for control of apple scab. In the present bulletin an attempt is made to present a general summary of the more important results obtained. The primary object of the experiments was to determine an efficient and economical control of apple scab with a minimum amount of injury to fruit and foliage, as applied under Maine conditions. With the different fungicides, arsenate of lead was added as an insecticide at the rate of 2 lbs. of paste or 1 lb. of powder to 50 gal. of solution.

A comparison was made of 3:3:50 Bordeaux mixture and a standard dilution of lime-sulphur which was equivalent to a 1 to 40 dilution of a 33° Baumé concentrate. Bordeaux mixture, while efficient in scab control, nearly always caused serious leaf injury, and sometimes resulted in a considerable russeting of the fruit. Lime-sulphur of standard dilution gave little leaf injury, but was somewhat less efficient in controlling the disease.

The effect of different dilutions of lime-sulphur was investigated, and a spray containing 25 per cent less of the concentrate than the standard dilution resulted in the appearance of more scab than where the standard dilution was used. A comparison was made between the standard dilution and one 20 per cent stronger for four successive seasons, and it appears that on the Ben Davis apple a solution of lime-sulphur at least 20 per cent stronger than the standard dilution can be used with comparative safety.

The importance of a first application at the time of the blossoming period was also tested, and while some increase was given during certain seasons, yet the general results indicated that failure to spray at this time did not greatly reduce the efficiency of subsequent applications.

Arsenate of lead used alone in the progress of these experiments was found to have considerable value as a fungicide. In some instances trees receiving arsenate of lead gave almost as good control as where the insecticide was used in combination with the fungicide.

Notes are given on the effect of strong fungicides used as a first application followed by arsenate of lead alone, and the effect of dormant sprays for insects used in combination with the regular summer sprays. A comparison was made between self-boiled lime-sulphur and other forms of this fungicide which indicates that it is less efficient than the dilutions made from certain commercial brands of lime-sulphur concentrate. A trial was made of copper-lime-sulphur which indicated that, so far as scab control is concerned, it is about as efficient as the same dilution of lime-sulphur, but the presence of copper resulted in considerable foliage injury. Extra fine sulphur flour was found to possess considerable fungicidal value.

Comparative tests were made of a number of proprietary spraying compounds. Sulfocide, while efficient in scab control, caused a considerable amount of

injury to the fruit. Soluble sulphur was tested two years, and while it proved an efficient fungicide, at the dilutions tested it is considered unsafe as a summer spray for apple foliage. Another proprietary compound used was atomic sulphur. This caused no injury to the fruit or foliage, and scab control and percentage of perfect apples was nearly the same as that secured with lime sulphur.

"Sooty blotch" of the pear, E. S. Salmon and H. Wormald (Gard. Chron., 3. ser., 59 (1916), No. 1518, pp. 58, 59, figs. 4).—Sooty blotch of pear and apple is described, with the differences apparent between these two hosts. It is considered probable that the disease is caused by Leptothyrium carpophilum, though the pycnidial stage of the fungus has not yet been found. The disease is distinguished from scab (Fusicladium) by the fact, among others mentioned, that the sooty blotch develops after the fruits are stored.

Crown gall on raspberries and blackberries, P. Thayer (Mo. Bul. Ohio Sta., 1 (1916), No. 7, p. 218).—An account is given of a study on the occurrence of crown gall on raspberries and blackberries. In 1911, 99 rows, including all the leading varieties of blackberries and raspberries, were planted, and in 1916 the plantation was dug out and the plants all inspected. Of the black and purple raspberries, not a single sound plant was found and all varieties of red and yellow raspberries were more or less subject to root gall, although there was considerable variation in the amount of infection. A marked immunity was shown by the blackberries. With the exception of a few nodules found on the variety Lawton and a few canes of McDonald not a single plant of the native varieties of blackberry was found affected.

[Grape diseases] (Bol. Agr. [São Paulo], 16. ser., 1915, Nos. 10, pp. 836-845; 11, pp. 921-936, figs. 4; 12, pp. 1017-1022, figs. 2).—Information is given regarding two fungus diseases of grape, Peronospora viticola and Oïdium tuckeri, which cause loss in São Paulo, also regarding their control by copper and other sprays employed in connection with these two diseases.

Citrus canker. F. A. Wolf (Alabama Col. Sta. Bul. 190 (1916), pp. 91-100, pls. 2, figs. 6).—In a previous publication, the author gave an account of investigations of citrus canker (E. S. R., 35, p. 152). The present publication contains a brief account of the more important results of these investigations, together with a compilation of information drawn from other sources.

A disease of the oil palm in the Belgian Kongo (Bul. Imp. Inst. [So. Kensington], 13 (1915), No. 3, pp. 479, 480).—Attention is called to a fungus thought to be identical with Ganoderma tumidum, attacking as a rule mature, but also sometimes young, palm trees in the Belgian Kongo. The fungus may persist after the death and disintegration of the tree. It is suggested that all diseased trees be totally destroyed and the affected area surrounded by a trench 2 ft. deep and treated with freshly slaked lime.

Septoria disease of chrysanthemum, R. LAUBERT (Handelsbl. Deut. Gartenbau, 30 (1915), pp. 17, 18; abs. in Ztschr. Pflanzenkrank., 25 (1915), No. 2, p. 118).—Besides noting a severe local attack of S. chrysanthemella on C. indicum in Zehlendorf in December, 1914, the author discusses the previous distribution and developmental conditions of this disease.

Causation and control of breaking sickness in tulips, C. Hammarlund (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 105 (1915), pp. 23, pl. 1, figs. 5; K. Landtbr. Akad. Handl. och Tidskr., 54 (1915), No. 2, pp. 89-109, pl. 1, figs. 5).—Giving an account of studies on tulips, which, after blooming normally, suddenly developed a break in the stem, the author claims that the trouble is due to means used to force development. Measures recommended to prevent the weakness are avoidance of very close planting, of excessive watering, and of a close, damp atmosphere in the hothouse.

Pathological observations on the chestnut in southern Indiana, J. R. Weir (Ann. Rpt. Ind. Bd. Forestry, 15 (1915), pp. 140-163, figs. 8).—The author has investigated the conditions in regard to the chestnut tree in southern Indiana for several years, primarily with reference to the chestnut bark disease, but information is given regarding the presence and habits of a large number of other fungi, mostly saprophytic, on chestnut, the chestnut blight fungus (Endothia parasitica) not having been found by him. A large amount of other information is presented regarding the forest growth.

The white pine blister rust, P. Spaulding (U. S. Dept. Agr., Farmers' Bul. 742 (1916), pp. 15, pl. 1, figs. 5).—A popular account is given of the white pine blister rust due to Cronartium ribicola, and the life cycle of the fungus through its host plants, white pines, currants, and gooseberries, is described. This disease, which has been introduced into this country from Europe, has spread rather extensively, 12 distinct new outbreaks having been observed in 1915. Suggestions are given for the control of the disease and the need of adequate state laws for its control is pointed out.

[Root disease of Para rubber], W. H. Johnson (Rpts. Agr. Depts. North. and South. Provs. [Nigeria], 1914, pp. 24, 31).—This report of the director contains an account of an outbreak of root disease in 1914 due almost exclusively to Polyporus lignosus, Hymenochæte noxia having been apparently eliminated by the removal in 1912 of all stumps known to be susceptible thereto.

A new disease in the Para rubber plantation at Calabar is due to a fungus believed to be *Ustulina zonata*, which in Ceylon causes a root disease of tea. The necessity for removal of the stumps is indicated.

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

A systematic account of the prairie dogs, N. Hollister (U. S. Dept. Agr., Bur. Biol. Survey, North American Fauna No. 40 (1916), pp. 36, pls. 7, figs. 2).—
The so-called prairie dogs (Cynomys spp.) are divided into two general classes, (1) the black-tailed prairie dogs which form the subgenus Cynomys, consisting of three forms of two species, and (2) the white-tailed prairie dogs which form the subgenus Leucocrossuromys, consisting of four forms of three species. Prairie dogs are distributed over a large part of the Great Plains and Rocky Mountain regions and are of considerable economic importance, due mainly to their destruction of grasses and other forage plants.

Entomology, A. W. Morrill (Arizona Sta. Rpt. 1915, pp. 563-565).—The work with the harvester ant (Pogonomyrmex barbata) was continued during the season of 1915. Where 28.5 lbs. of London purple were required per acre in 1914 (E. S. R., 33, p. 57) only 2.5 lbs. were required in 1915 in the work of cleaning up the remnants of the old nests. The experiment shows that when once brought under complete control, the ants can be held to a point where they do no damage at a total cost each year of less than 40 cts. an acre.

Brief mention is also made of the work with the green June beetle (*Allorhina mutabilis*) and the clover or alfalfa seed chalcid fly. A trap border experiment with the latter, though carried on under unfavorable conditions, appears to have shown definite results.

Entomological investigations, 1915, L. CHILDS (Oregon Sta., Rpt. Hood River Sta., 1915, pp. 47-61, figs. 2).—The investigations here reported relate largely to the fruit tree leaf roller (Archips argyrospila) and to codling moth control work in 1915.

In experimental control work with *A. argyrospila* the best results were obtained from the use of lead arsenate at the rate of 6 lbs. to 50 gal. of water. Miscible oil also gave highly satisfactory results, and while more expensive

"the marked increase in efficiency attained with the oil more than warrants its use. For complete safety to the foliage, the oil applications should be made before the buds burst. Apparently no permanent injury occurred in our experimental plats this season from the late applications, but the margin of safety is extremely small and such a procedure should not be generally followed."

Codling moth infestation was very severe during 1915 throughout the entire Northwest, the loss from this source in the Hood River Valley being about twice that of 1914. In response to inquiries relative to the advisability of mixing the arsenate of lead with the fungicides, investigations were conducted with arsenate of lead in combination with lime-sulphur and iron sulphid, lime-sulphur and atomic sulphur, lime-sulphur and barium tetrasulphid, and with milled sulphur and Bordeaux mixture. In no case was the efficiency of the poison descreased.

It was found that during the year the greater percentage of worms entered the fruit through the side rather than at the calyx end. Experiments conducted show clearly that one application, whether it be the "calyx" or the one preceding the hatching of the eggs, will not control the moths. The station recommends two different schedules of sprays for the season of 1916. "The first two applications will be the same in both cases—that is, the calyx and '30-day' spray for the control of the first brood of worms. Where a loss of not more than 8 per cent was experienced in 1915, one well-timed summer spray should prove very effective in controlling the second generation. This should be applied in early August. The date will be dependent upon weather conditions. . . . Where the infestation during 1915 was found to be more than 8 or 10 per cent, two summer applications should be made to control the codling moth. The third spray should be made about July 20 and the fourth toward the middle or last of August."

Observations relating to the woolly aphis and strawberry root weevil are also briefly noted.

The locust borer (Cyllene robinice) and other insect enemies of the black locust, H. Garman (Kentucky Sta. Bul. 200 (1916), pp. 99-135, pls. 22, fig. 1).—The data here presented have previously been noted from another source (E. S. R., 35, p. 355).

Two troublesome pests of man, R. D. Whitmarsh (Mo. Bul. Ohio Sta., 1 (1916), No. 7. pp. 221-224, figs. 2).—Brief accounts are given of chiggers and sandflies and methods of prevention and control.

Aleyrodidæ, or white flies attacking the orange, with descriptions of three new species of economic importance, A. L. QUAINTANCE and A. C. BAKER (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 12, pp. 459-472, pls. 6, figs. 3).—This paper brings together information on the distribution and food plants of the white flies which attack citrus plants, 16 in number, of which 3 of economic importance are described as new to science, namely, Aleurocanthus citriperdus from Ceylon, India, and Java; A. woglumi from India, Ceylon, Cuba, Jamaica, the Bahamas, and the Philippines; and Aleurothrixus porteri from Chile and Brazil.

A list of 20 references to the literature cited is included.

Studies of life histories of leafhoppers of Maine, H. Osborn (Maine Sta. Bul. 248 (1916), pp. 53-80, pls. 5, figs. 8).—This bulletin presents the results of studies made during the summer of 1914 in continuation of those begun in 1913 and previously reported upon (E. S. R., 33, p. 356).

A chemical analysis made of timothy by the station chemist indicates that the leafhoppers not only reduce the quantity but lessen the food value of the crop attacked.

Eight species are here considered, namely, Cicadula sexnotata, Acocephalus albifrons, A. striatus, Chlorotettix unicolor, Idioeerus provancheri, Dræculacephala angulifera, Phlepsius apertus, and Balclutha punctata, of which the first three mentioned are dealt with at some length. The six-spotted leafhopper (C. sexnotata), one of the first to invade new fields, produces several generations and is quite migratory in habit. After this, for Maine, Deltocephalus minki appears to be one of the earliest to appear in open fields, and later the froghoppers and A. striatus come in abundance. One of the latest and perhaps the least migratory is A. albifrons, termed the timothy crown leafhopper, since it lives down in the ground around the crowns of timothy.

The army worm in New York in 1914 (Leucania unipuncta), H. H. KNIGHT (New York Cornell Sta. Bul. 376 (1916), pp. 751-765, pls. 8).—Next to the serious outbreak of the army worm in 1896, studies of which were made by Slingerland (E. S. R., 9, p. 365), the outbreak in 1914 was the most serious that has occurred in New York State. This outbreak afforded an opportunity to gather considerable additional data, which are here reported.

The observations relate to food plants, place of development in Genesee County, life cycle, occurrence in 1915, natural enemies and methods of control, and the occurrence of an allied species, *L. pseudargyria*.

Comparative study of the amount of food eaten by parasitized and non-parasitized larvæ of Cirphis unipuncta, D. G. Tower (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 12, pp. 455-458).—In the author's experiment with the parasite Apanteles militaris it was found that the parasitized army worm ate approximately half as much as unparasitized larvæ during the same periods, and it seems conclusive that parasitism by A. militaris is directly beneficial in the generation attacked. "From the results obtained it might seem as though larvæ oviposited in at an earlier date would eat more before being killed, but the time spent in the host by the parasites seems to be fairly constant, and this was also noticed in a larger number of cases in former experiments with A. militaris. Hence, it is believed that in such cases the larvæ would have only approximately the same amount of time for feeding, and a larger portion of this period would occur during the earlier stages, when a much smaller amount of food is eaten, so that the amount eaten would be less than the normal for unparasitized larvæ."

The clover leaf tyer (Ancylis angulifasciana), H. A. Gossard (Ohio Sta. Bul. 297 (1916), pp. 427-443, pls. 2, flys. 2; abs. in Mo. Bul. Ohio Sta., 1 (1916). No. 6, pp. 181-185, flys. 2).—The author reports observations made of this insect since 1905, in the spring of which year his attention was drawn to the ragged. eaten condition of the clover leaves. Considerable damage was caused to clover at the station farm. Its appearance in injurious numbers seems to have been local, since the author has not observed it to be of importance elsewhere than at Wooster.

Red clover and alsike are said to have been very freely attacked in the field, white clover less commonly, and alfalfa not at all. Clover foliage eaten by the caterpillars presents a ragged appearance, the epidermis from one of the surfaces being either partly or wholly eaten away, while that remaining appears thin, papery, and white, except for minute splotches and streaks of green here and there. Either the upper or lower surface will be eaten, whichever happens to be turned inward in the cell.

The moths of the first brood appear in late April or early May and are nearly all gone by May 20. The eggs were found to require an incubation period of from two to three weeks. Three broods were observed.

"It is apparent that the first clover harvest, coming in late June and early July or earlier, will carry to the mow many of the larvæ and pupæ of the first

brood and that the second cutting will take off most of the second brood pupæ. Fall pasturage will destroy many of the third brood. Plowing old clover stubble in the spring preparatory to planting corn practically exterminates all larvæ in the field. The present well-established customs for harvesting and pasturing clover furnish a logical and effective program of control."

Effect of Roentgen rays on the tobacco, or cigarette, beetle and the results of experiments with a new form of Roentgen tube, G. A. RUNNER (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 11, pp. 383-388).—This is a report of studies conducted in continuation of those previously noted (E. S. R., 29, p. 359).

"Under laboratory conditions, tests made with a Roentgen-ray tube permitting a high-energy input and giving an intense and powerful radiation gave results which promise that the X-ray process may be successfully used in treatment of cigars or tobacco infested with the tobacco, or cigarette, beetle. Heavy dosages must be given, as is indicated by the exposure given in the series of experiments tabulated in this paper. In treatment of the egg stage, heavier exposures are required to sterilize eggs which are near the hatching point than are required to sterilize eggs newly laid. In experiments performed by the writer a dosage equivalent to 150 milliampere minutes exposure with a spark gap of 5.5 in. gave satisfactory results with eggs in tobacco placed 7.5 in. from the focal spot of the tube. With this exposure the eggs in which embryonic development was well advanced hatched, but in all cases where these larvæ were kept under observation they failed to reach the adult stage. The minimum lethal dosage at a given distance from the focal spot of the Roentgen tube used has not been determined.

"In two separate experiments adults were given an exposure of 600 milliampere minutes (amperage  $\times$  time), with a spark gap of 5.5 in., giving an approximate voltage of 65,000, with humidity at 57. The distance from the focal spot of the Roentgen tube was 7.5 in. The results are as follows:

"(1) No effect on length of life was apparent, as the beetles died at about the same rate as the same number of beetles kept as a check. (2) Large numbers of eggs were deposited after exposure. These eggs were infertile. Eggs laid by the check beetles hatched normally.

"Larvæ were given an exposure of 600 milliampere minutes, other conditions of the experiment being the same as in the experiments with adults given above. While no immediate effect was apparent, the treatment had the effect of stopping activity and development, the larvæ remaining in a dormant condition for a prolonged period. All treated larvæ died before reaching the pupal stage."

The alfalfa weevil and methods of controlling it, G. I. Reeves, P. B. Miles, T. R. Chamberlin, S. J. Snow, and L. J. Bower (U. S. Dept. Agr., Farmers' Bul. 741 (1916), pp. 16, figs. 7).—A popular summary of knowledge of this insect and means for its control.

Cotton boll weevil control in the Mississippi Delta, with special reference to square picking and weevil picking, B. R. Coad (U. S. Dept. Agr. Bul. 382 (1916), pp. 12).—In plat tests of five square pickings at 7-day time intervals an increase of 23 per cent over the check was obtained. Tests of seven weevil pickings with the bag-and-hoop indicated similar results. Comparative observations on different methods of collecting weevils demonstrated the great superiority of the bag-and-hoop over hand picking so definitely that there should be no question as to which method to follow. The margin of profit to be derived from these two control measures seems to be too slight to allow their operation on a wage basis. For this reason the only condition under which they should be attempted is on tenant cotton where the work can be performed without any direct outlay for labor.

House ants: Kinds and methods of control, C. L. MARLATT (U. S. Dept. Agr., Farmers' Bul. 740 (1916), pp. 12, figs. 5).—This is a more extended account than that previously noted (E. S. R., 10, p. 654).

# FOODS-HUMAN NUTRITION.

The iodin content of foods, E. B. Forbes (Mo. Bul. Ohio Sta., 1 (1916), No. 7, pp. 219, 220).—The author concludes from his study of the iodin content of various foodstuffs that iodin is a comparatively unusual food constituent, and that its presence is commonly accidental in the sense of standing in no essential relation to the growth of the food products. Variations in the iodin content of foods were not successfully related to any associated conditions. No consistent or orderly geographic distribution of iodin in foods was revealed, nor were there noticeable effects of the type of soil or method of fertilization on the iodin content of foods. The iodin content of samples of the same crop from different plats of the same field sometimes varied greatly.

The relation of certain physical characteristics of the wheat kernel to milling quality, C. H. Bailey (Jour. Agr. Sci. [England], 7 (1916), No. 4, pp. 432-442).—The investigations here reported indicate that, with the same type and variety of wheat, kernel volume, because of its relation to the ratio of endosperm to nonendosperm structures, varies directly with the potential flour yield.

"Accurate determination of kernel density must include the complete removal of all mechanically held air. Large kernels, other things being equal, have a higher specific gravity than small kernels of the same variety, indicating the endosperm to have a higher specific gravity than the bran and germ.

"Relative density of the endosperm is generally conceded to be dependent upon the proportion and size of the air vacuoles. Soft, light-colored, yellow-berry kernels have a lower specific gravity than hard, dark-colored kernels of the same variety. The more dense the endosperm, other things being equal, the greater the ease of, and the more complete, the separation of endosperm from bran and germ in milling.

"Wheat kernels of a high specific gravity have a higher nitrogen content as a usual thing than less dense kernels of the same relative size or volume.

"Hard red wheats grown in the northern Great Plains area, while varying widely, have a higher average specific gravity than do the soft red winter wheats grown in the eastern half of the United States."

Milling and baking tests on Argentine and Walla wheats, P. R. Scott and F. G. B. Winslow (Jour. Dept. Agr. Victoria, 13 (1915), Nos. 11, pp. 661-666, fig. 1; 12, pp. 736-739).—These tests of wheats imported from Argentina and the Pacific Coast States of this country indicated that, as compared with Australian wheats, the flour produced was lacking in bloom and the dough required a longer time to prove and lacked the power to produce as good loaves. When blended with a moderate percentage of Australian wheat flour, good loaves were obtained.

A method of making bread. G. CORNALBA (Bul. Agr. [Milan], 50 (1916), No. 27, p. 1).—This article describes a system of bread making which utilizes all of the substance of the grain. The grain is submitted to germination for from 50 to 60 hours, macerated to soften it, ground, mixed with yeast and salt, and then made into a dough. This dough is made homogeneous, divided into loaves weighing about 50 gm., and baked in the usual manner.

The bread is said to have a very dark color, a rough crumb, a heavy crust, and an agreeable and pronounced taste. One hundred kg. of the wheat give about 135 kg. of bread containing about 35 per cent of water, which makes the

weight of the bread a little greater than that of the wheat. It is stated that this system of bread making has the further advantage of utilizing nutritive material which is lost in other methods—e. g., protein, phosphoric acid, lecithin, phytin, organic phosphorus compounds, magnesium salts, and diastatic ferments.

Some factors affecting the cooking of dholl [red gram or pigeon pea] (Cajanus indicus), B. VISWANATH, T. L. Row, and P. A. R. AYYANGAR (Mem. Dept. Agr. India, Chem. Ser., 4 (1916), No. 5, pp. 149-163, pl. 1, fig. 1).—The factors which were studied with reference to their influence upon the rate of cooking of dholl (C. indicus) included the composition of the water, the fat content, the variety, and the method of preparation. The results of the investigation are summarized in part as follows:

"Dissolved salts, such as are found in natural waters, exert a marked influence on the time taken to cook dholl. Calcium and magnesium salts and the chlorids of hydrogen and sodium exert a strong retarding effect, whereas alkalis and alkaline carbonates have the reverse action. Whether the action exerted by any salt is a retardation or an acceleration, the effect is approximately proportionate to the concentration, i. e., the harder the water the slower is the rate of cooking. The addition of sodium bicarbonate or sodium carbonate to a hard water materially hastens the cooking.

"The rate of cooking of dholl is approximately proportionate to the rate of solution of the dholl substance—i. e., to the rate of solution of the proteid and starch. The proportion of proteid to starch dissolved is not constant but varies with different solutions. Alkalis and alkaline carbonates dissolve a greater proportion of proteid than starch as compared with pure water, whereas hydrochloric acid dissolves a greater proportion of starch. In addition, alkalis and alkaline carbonates greatly accelerate the rate of cooking.

"The rate of solution of the proteid appears to be the factor which mainly controls the rate of cooking. . . . The fat content plays a very unimportant part. . . . Dholls of different localities have varying rates of cooking."

In connection with the investigation a study was made of the influence of different salts on the liquefaction of pure starch.

Cultivation and canning of mangoes in India, T. C. CHAUDHURI (Jour. Indus. and Engin. Chem., 8 (1916), No. 7, pp. 618, 619).—The author discusses briefly the use of mangoes as food, methods of cultivation, and the problems involved in preserving the fruit.

Case of poisoning by daffodil bulbs (Narcissus pseudo-narcissus), W. G. McNab (Pharm. Jour. [London], 4. ser., 42 (1916), No. 2738, pp. 367, 368).—In this article and its discussion, references are made to several cases of food poisoning caused by eating the bulbs of the common daffodil, these being mistaken for onion and used in the preparation of stews. Severe gastro-intestinal disturbances were experienced but no deaths resulted. It is stated that daffodil bulbs contain an alkaloid whose physiologic action differs according to the stage of growth of the plant.

The investigation of some cases of cheese poisoning, G. Spica (Atti R. Ist. Veneto Sci., Let. ed Arti, 69 (1909-10), pt. 2, pp. 685-691).—Cases of food poisoning attributed to cheese are reported. Four samples of the cheese in question were examined. Extraction with water and ether yielded a substance of unknown chemical composition which was toxic to frogs.

The soy bean and condensed milk in infant feeding, J. Ruhräh (Amer. Jour. Med. Sci., 150 (1915), No. 4, pp. 502-512).—The author reports the results of clinical experience and concluded that the soy bean, condensed milk. and some cereal (as a source of additional carbohydrate) in proper proportions may be used without danger.

On the composition of human milk in Australia.—I, The composition during the early stages of lactation, H. S. H. Wardlaw (Jour. and Proc. Roy. Soc. N. S. Wales, 49 (1915), pt. 2, pp. 169-198, ftg. 1).—In this extensive investigation a study was made of the composition of 105 samples of human milk obtained during the first 10 or 11 days after childbirth.

In addition to determining the most probable composition of human milk, it was the object of the author to determine the effect of a number of factors upon its composition. It was found that certain values of the percentages of constituents other than fat occurred more frequently than others. These were total solids, 12.8 per cent; solids not fat, 9.8 per cent; protein, 1.9 per cent; solids not fat and not protein, 7.6 per cent. The percentages of fats vary widely, the average content being 3.14 per cent. "The average percentage of fat increased from 2.84 to 4.13 during the first 11 days of suckling; the average percentage of protein decreased from 3.3 to 1.69 during the same period.

"The age of the woman, the number of pregnancies, the volume of the sample, the time since the last withdrawal of milk from the breast, and the breast from which the sample was taken appeared to have no distinct effect on the composition of the milk examined."

A bibliography of cited literature is appended.

Bulletin of the inspection of foods and beverages in Surinam.—Fish Analyses, J. Sack (Keuringsdienst Eet- en Drinkwaren Suriname, Bul. B (1916), pp. 34).—Data are given showing the percentage composition of the edible portion and the cost of a number of kinds of fish.

The percentage of alcohol in homemade root beer, C. H. La Wall (Amer. Jour. Pharm., 88 (1916), No. 8, pp. 355-358).—The homemade root beer, prepared according to directions, was found to contain 0.25 per cent of alcohol after standing 2 days and 1.52 per cent after standing 11 days. No higher alcoholic content was observed after the beer had stood for 10 days longer. If the fermenting liquor was allowed to stand 3 hours before bottling and the bottles were only partially filled, the alcoholic content rose more rapidly, and the highest amount noted was 1.77 per cent.

The inhibiting action of certain spices on the growth of micro-organisms, FREDA M. BACHMANN (Jour. Indus. and Engin. Chem., 8 (1916), No. 7, pp. 620–623, figs. 2).—The organisms studied in this investigation were pure cultures of species of the common molds, Rhizopus, Penicillium, Aspergillus, and Alternaria (which are frequently found on spoiled preserves), and pure cultures of Bacillus coli, B. prodigiosus, and B. subtilis. The spices tested were added in some form to the nutrient agar in which the bacteria or molds were grown. Studies were made of the effect of alcoholic extracts of spice, ground spice, spice and vinegar, cinnamic aldehyde and eugenol (the active principles of cinnamon and cloves), the oils of allspice and nutmeg, and the oleoresin of black pepper.

The author states that "it does not appear from the extent of the present study that spices as used in the kitchen in the usual amounts for flavoring purposes in spiced cakes exert a very considerable preservative effect. Where cinnamon, cloves, and allspice are used in large amounts, the growth of molds may be retarded. In spiced fruit where a large amount of the spice is used, the preservative effect may be much greater. This effect may be greater, too, when the spice is combined with vinegar."

It is suggested that cinnamic aldehyde and possibly other active principles might be used in such proportions as to prevent the growth of micro-organisms and yet in small enough quantities not to spoil the flavor of the product.

"Pepper and nutmeg have little effect on the growth of micro-organisms. A mixture of nutmeg and water boiled for a half hour and left exposed to the air for chance inoculation was covered with various molds in less than a week. Cloves and allspice in large amounts are quite effective in preventing the growth of molds and bacteria, and cinnamon is the most effective of the spices; this is true of the ground spices, their essential oils, and the alcoholic extracts."

The dairy and pure food laws of the State of Connecticut ([Hartford, Conn.]: Office Dairy and Food Conr. [1916], pp. 52).—The text of the laws is given as corrected to the close of the legislative session of 1915.

[Food and drug analyses], J. P. Street et al. (Connecticut State Sta. Rpt. 1915, pt. 5, pp. 265-419).—This report presents the results of the analysis of 2,220 samples of foods and drugs, of which 1,081 were not adulterated. The food products examined included cereal breakfast foods, cheese, cocoa and chocolate preparations, coffee, coffe substitutes, diabetic foods, fig preparations, flavoring extracts, canned fruits, infant foods, sirups, etc. Full analytical data are given regarding each of the samples analyzed. The drug products examined included standard drug preparations and proprietary medicines.

Bulletin of the inspection of foods and beverages in Surinam.—Analyses of common foods, J. Sack (Keuringsdienst Eet- en Drinkwaren Suriname, Bul. C (1916), pp. 12).—In this bulletin analytical data are reported concerning the composition of some well-known meats, vegetables, and fruits.

Rates for electric cooking and water heating (Jour. Electricity, 37 (1916), No. 1, pp. 12, 13).—The question of proper rates for this class of service is discussed and the rates of several western companies are given as illustrations.

Canning in glass in the home (fruits, vegetables, and meats), SARAH E. BELT (Agr. of Mass., 63 (1915), pt. 2, pp. 49-57).—General information and specific directions are given for the canning of fruits, vegetables, and meats.

Interim report of the departmental committee appointed by the president of the board of agriculture and fisheries to consider the production of food in England and Wales, Milner et al. (London: Govt., 1915, pp. 7).—A number of measures are recommended for increasing the present production of food, on the assumption that the war may be prolonged beyond the harvest of 1916.

Food economics, G. Lusk (Jour. Wash. Acad. Sci., 6 (1916), No. 12, pp. 387–396).—This lecture presents statistical data showing the amount of protein and the fuel value of food consumed by people living under extremely varied conditions.

It also includes a brief statement of the results of a dietary study by F. C. Gephart, carried out at a private boarding school for boys having 355 students, in which determinations were made of the food supplied per meal, the proportion of the total number of calories furnished by the different foods, the cost of the food, and the amount of waste. The author states that the growing athletic boys in this school were not satisfied with 3,000 calories daily, but took 4,350 calories daily at the table and also bought 650 additional calories at a neighboring store. In his opinion these results show that active boys eat more food than is realized and that their ravenous appetite is due to the muscular work involved in their play and that "lack of appreciation of this factor and lack of provision for it are the probable causes of much of the undernutrition seen in children of the school age."

The importance is emphasized of including on the label a statement of the number of calories furnished by packages of foods.

Conditions of diet and nutrition in the internment camp at Ruhleben, A. E. TAYLOR (London: Govt., 1916, pp. 12).—The data presented in this report are based on a 7-day study of the dietary in the camp.

The following requirements are given for a complete, sufficient, and normal diet: "It must contain protein sufficient in amount and representative in component amino acids to maintain the tissues and cells of the body in a state of normal composition and function. . . . It may be stated that from 70 to 90 gm. of protein per day are fully competent to maintain normal nutrition in the adult male (not engaged in hard work), provided that the proteins offer the body all the needed amino acids and that the diet is rich in carbohydrate."

The diet should also contain a sufficient amount of fuel (largely in the form of carbohydrate) to furnish at least 30 calories per kilogram of body weight per day. It must contain from 25 to 50 gm. of fat per person per day, the various salts required in the body, and certain unknown substances grouped under the term "vitamins," and it should not consist entirely of preserved or conserved foodstuffs.

In addition, the author lays considerable emphasis on the fact that the diet to be entirely adequate must take into some account the habits, tastes, and customs of the persons fed. It is pointed out that diets tolerated under normal conditions may become intolerable under conditions of confinement and that monotony of the diet should be avoided, since it may lead to reduced appetite and consequently impaired nutrition. Monotony of the diet is less noticeable if it is one to which the individual has been accustomed.

As a result of this investigation a number of changes in the diet of the camp are recommended and embodied in this report.

Review of the literature on the metabolism of normal infants, W. McK. MARRIOTT (Amer. Jour. Diseases Children, 12 (1916), No. 1, pp. 88-102).—In this summary and digest of data the results obtained by a number of investigators on different phases of this subject are brought together. Most of the material has been previously noted from the original sources.

The question of cellulose digestion, W. Ellenberger (Hoppe-Seyler's Ztschr. Physiol. Chem., 96 (1915), No. 3, pp. 236-254).—A preliminary note discussing the factors which influence cellulose digestion.

The antiseptic action of the gastric juice, J. P. Gregersen (Centbl. Bakt. [etc.], 1. Abt., Orig., 77 (1916), No. 4, pp. 353-361).—The object of these experiments was to determine the influence of the acidity of the gastric juice upon its bactericidal action and whether or not any other factors were involved. Samples of the gastric contents were obtained from a number of individuals 45 minutes after the ingestion of an Ewald test meal (35 gm. of toast and 250 gm. of water), the acidity of the contents measured by titration, and the bactericidal property determined, Staphylococcus pyogenes aureus being the organism used. In some of the samples different degrees of acidity were secured by the addition of hydrochloric acid or sodium hydroxid before determining the bactericidal property.

It was found that the bactericidal power of the stomach contents varied directly as the amount of free acid present and was not influenced by the combined acidity or the amount of pepsin present. The bactericidal action of the gastric juice was from 3 to 4 times as strong as corresponding strengths cothe pure acid in water.

The presence and significance of molds in the alimentary canal of man and higher animals, G. Turesson (Svensk Bot. Tidskr., 10 (1916), No. 1, pp. 1-27).—This article reports the results of the isolation and investigation of molds in samples of feces from 13 different persons, two of whom were vegetarians. In addition to determining the species present investigations were

made of the action of temperature and gastric juice upon the spores of Penicillium and Aspergillus and the pathogenic properties of molds isolated from human and animal feces by means of intravenous injections and feeding experiments made on laboratory animals.

In summarizing the results of the investigation, the author states in part that "the occurrence of fungi in the alimentary canal of man has been proved to be more frequent than was formerly supposed. In analyzing samples of human feces the following molds were isolated: A. fumigatus, A. flavus, A. niger, A. nidulans, A. umbrinus, A. terreus, P. divaricatum, O'dium lactis. In addition numerous yeasts were found. . . .

"The temperature modifies the toxic action of the gastric juice in this way: An increase in temperature above the optimum for the fungus increases the toxicity of the juice to the species. Molds with low optima are, therefore, killed when passing t'rough the alimentary canal, while thermophilous species pass through alive. Accordingly, only molds with comparatively higher optima are found in feces of warm-blooded animals while feces of cold-blooded animals yield molds with low optima as well.

"Intravenous injections in rabbits of A. terreus, A. umbrinus, and P. divaricatum showed no pathogenic properties of these molds.

"Feeding of spores and mycelium of A. fumigatus, A. flavus, A. niger, A. nidulans, A. umbrinus, A. terreus, P. avellaneum, and P. divaricatum to rabbits proved to be fatal. The symptoms of poisoning from the toxic molds were muscular convulsions resembling tetanus, weakness, and paralysis, followed by death.

"An accumulation of molds in the alimentary canal of man may lead to serious disturbances and should, therefore, receive due attention."

A bibliography of cited literature is appended.

Chemical changes in the central nervous system as a result of restricted vegetable diet, Mathier L. Koch and C. Voestlin (Pub. Health Serv. U. S., Hyg. Lab. Bul. 103 (1916), pp. 5-49, figs. 12).—The small amount of experimental data available regarding the chemical changes produced in the central nervous system as the result of changes in diet shows that underfeeding with a mixed diet leads to no marked changes except a high variation in the water content, that starvation does not appear to change the composition of the brain, and that an exclusive diet of polished rice leads to a decrease in the amount of nitrogen and phosphorus in the brains of pigeons.

In this investigation six laboratory animals (monkeys) were fed upon the following diets: (a) Corn-oil cake, a substance poor in vitamin; (b) equal parts of corn meal and sweet potatoes, a diet rich in carbohydrates and poor in protein and fat; (c) corn meal; and (d) raw carrots. From a comparison of the chemical composition of the encephalon and spinal cord of these six monkeys with the composition of the encephalon and spinal cord of a normal monkey maintained on a mixed diet as a control, the following conclusions are drawn:

"Chemical changes in the brain and cord are observed in animals (monkeys and rats) as the result of an exclusive vegetable diet of various composition.

Histological examination of the central nervous system of these animals reveals extensive degeneration of many nerve tracts in the spinal cord, very similar to those found in pellagra.

In some of the animals the chemical changes are practically identical with the changes observed in pellagra. These findings therefore yield additional evidence for the theory that pellagra is a dietary disease."

Chemical changes in the central nervous systems in pellagra, Mathilde L. Koch and C. Voegtlin (Pub. Health Serv. U. S., Hyg. Lab. Bul. 103 (1916),

pp. 51-129. pls. 2, figs. 3).—In this report the work of other investigators on the subject is briefly reviewed, and a short summary of the present-day knowledge of the chemical constituents of the nervous system is given. The analytical methods employed are described in detail. A comparison of the chemical analysis of the central nervous system in five cases of uncomplicated pellagra, as compared with the chemical analysis of normal controls, showed that in pellagra the central nervous system is subject to a series of chemical changes involving, principally, certain lipoids.

## ANIMAL PRODUCTION.

The production coefficients of feeds, G. S. Fraps (Texas Sta. Bul. 185 (1916), pp. 5-16).—It is stated that the value of a feeding stuff consists in its volume, which satisfies the appetite of the animal, its digestible protein, which furnishes material for muscular and other similar tissue, and its productive value, which represents its value for the purpose of supplying energy for work, or bodily activities, heat, or material for the production of fat, etc. This bulletin describes a method of calculating the productive values of feeds from their chemical composition.

The productive value of a feed is defined as the amount of fat that the feed will produce upon a fattening animal, when it is fed in addition to a basal ration already sufficient for the bodily needs of the animal. The author prefers to express the productive value in terms of fat for the reason that it represents as nearly as is possible the exact substance measured in the experiments, and does not involve any assumption as to the quantity of productive energy consumed in forming fat, or other similar assumptions. Knowing the composition and coefficients of digestibility the productive value in terms of fat of a given feeding stuff may be calculated, but in order to simplify the calculation it is proposed to use a factor to be known as the production coefficient. This is defined as the factor which, multiplied by the percentage of the nutrient, gives the productive value of that nutrient in terms of fat.

As the production coefficient is calculated from the coefficient of digestibility, anything that will affect the digestion will also affect the production coefficient. Also, some feeds may be regarded as mixtures of two or more constituents which have different coefficients of digestibility and different production values. Cotton-seed meal, for example, may be considered as composed of cotton-seed kernel residue and cotton-seed hulls, and the amount of cotton-seed hulls may be calculated from the amount of crude fiber present. Since cotton-seed kernels and cotton-seed hulls have different production coefficients, the quantity of crude fiber will thus affect the production coefficient of the feeding stuff.

There are similar variations in the composition of other feeding stuffs which are related to different constituents having different digestive coefficients and different productive values. These are problems which are under study.

A table is given which shows the production coefficients of a number of feeds, based upon the average coefficients of digestibility. A column is included which shows the method of correction used for the crude fiber, or nitrogen-free extract, or both, as the case may be.

[Feeding stuffs], F. A. Clowes (Hawaii Sta. Rpt. 1915, pp. 51-53).—Honohono (Commelina nudiflora) is described as an extremely succulent feed, much relished by cattle. Cattle fatten and produce an abundance of milk when pastured where it is plentiful. The total yield of green feed per acre, calculated from an experimental plat 10 ft. square, was 223.6 tons. Per acre production it compares very favorably with green alfalfa both in protein and in other food constituents.

It is stated that as a pasture grass *Paspalum dilatatum* has given excellent results. Its strong deep root system enables it to withstand the tramping of stock in wet weather better than any other grass tested that is equally relished by the cattle.

Cane-top silage has proved of value in feeding operations. Some of the cane tops were cut two weeks before they were put into the silo. Notwith-standing the resulting staleness and the excessive amounts of water that went into the silo during filling, the silage was of fair quality and was eaten readily by the cattle and horses. The yield of cane tops per acre is about 10 per cent of the weight of the usable cane, and on the unirrigated plantations this by-product would run from 4 to 8 tons of cane tops per acre.

Commercial feeding stuffs, 1915, J. P. Street et al. (Connecticut State Sta. Rpt. 1915, pt. 4, pp. 233-264).—Analyses are given of the following feeding stuffs: Cotton-seed meal; linseed meal; wheat bran, middlings, and shorts; cracked corn meal; corn gluten meal; corn gluten feed; hominy feed, dried brewers' grains; dried distillers' grains; dried beet pulp; mangels; coconut meal; peanut meal; oats; provender; alfalfa; alfalfa meal; cracker wastes; and various mixed and proprietary feeds.

Facts for the feed buyer, W. H. Strowd (Wisconsin Sta. Bul. 267 (1916), pp. 56).—Information regarding feeding stuffs is summarized, and analyses are given of the following: Cotton-seed meal, linseed meal, gluten feeds, corn oil meal, distillers' grains, hominy feed, corn germ meal, wheat bran and middlings, red dog flour, germ middlings, oatmeal and rye middlings, barley shorts, buckwheat bran, malt sprouts, dried brewers' grains, dried malt grains, alfalfa meal, blood and meat meal, meat scrap, bone products, tankage, ground peas, flax shives, silage, soy bean hay, and various mixed and proprietary feeds.

[Nutrition investigations at the Wisconsin Station] (Wisconsin Sta. Bul. 268 (1916), pp. 36-42, figs. 2).—Notes on several studies are given.

Value of proteins from different sources [for growth], by E. V. McCollum.—Since various unbalanced proteins are not all deficient in the same amino acids, it might be expected that when two unbalanced proteins were combined the first might supplement the deficiencies of the second and better growth be made than with either alone. To study this problem young pigs were fed on many rations in which either a single feed or two or more feeds mixed in various proportions supplied the protein.

Of those tested the proteins of milk were found most efficient for growth, the pigs storing in their bodies over 60 per cent of the milk protein. The proteins of the cereal grains had an efficiency of only from 23 to 28 per cent, and of linseed meal, fed alone, only 18 per cent. However, when three-fourths of the protein in the ration came from the corn and one-fourth from linseed meal the efficiency was increased to 37 per cent. From this it is concluded that linseed meal and corn are not deficient in the same amino acids, and that when combined one tends to correct the deficiencies of the other. This agrees with the good results secured in numerous scientific trials and in practice when linseed meal is fed as a supplement to corn. On the other hand, no better results were secured when wheat and wheat embryo were combined than when each was fed separately. In this case each feed is evidently deficient in the same amino acids, and one can not supplement the other.

Value of proteins from different sources [for milk production], by E. B. Hart and G. C. Humphrey.—It has been found in metabolism experiments with dairy cows that proteins from various sources are likewise of different worth for milk production. In these trials cows were fed a basal ration of corn stover, which supplied but a small amount of digestible protein. To this ration were added

corn grain and corn by-products, or wheat grain and by-products (much of the protein of which is unbalanced in composition), or milk protein, supplied in the form of skim-milk powder and casein (furnishing proteins which are well balanced in composition).

The percentage of the digestible protein of these rations which was used by the cows for milk production and the formation of body protein was 40 per cent with the corn ration, 34 per cent with the wheat ration, and 58 per cent with the milk protein ration. Such complete proteins as are furnished by milk are thus apparently of high efficiency for milk production.

Commonly unappreciated factors in food, by E. V. McCollum.—Previous experiments (E. S. R., 31, p. 864) have demonstrated that certain fat-soluble substances found in milk fat, fats from egg yolk, corn grain, and wheat embryo, and the soft portion of beef fats are necessary in the diet for continued growth. It appears that there is also required another class of substances which are soluble in water, the nature of which has not been discovered. These substances have been found thus far in egg yolk and wheat embryo, and are probably present in corn. Growing rats fed a ration of highly purified casein, egg albumin, dextrin, mineral matter, and milk fat failed to grow. However, normal growth took place when the water extract of wheat embryo was added, which evidently supplied the necessary accessory to the diet. It has been found that neither the fat-soluble nor the water-soluble accessories are injured by heating above the boiling point of water.

Influence of strictly regetable diets on growth and reproduction, by E. B. Hart and E. V. McCollum.—It is thought that strictly vegetable foods might be found insufficient for normal growth. To study this problem experiments were carried on with growing pigs kept in pens away from the soil and supplied in some cases with distilled and in others with natural water. On a well-balanced concentrate mixture of oats, corn, wheat, and oil meal, pigs failed to grow after about three months, even when sugar beets and alfalfa hay were supplied two or three times a week. Where but 1 per cent of meat scrap was added to the ration the pigs grew normally, reaching a weight of 250 lbs. by the time those on the strictly vegetable diet had reached 100 lbs.

Other experiments, however, showed that the missing essential constituents could be supplied in vegetable feed. In the earlier experiments uncut alfalfa hay was offered the pigs, but they consumed very little. Fifteen per cent of finely ground alfalfa meal was then mixed with the ration, so that the pigs would be forced to consume larger amounts of alfalfa. On this vegetable ration good growth occurred. These experiments indicate that the meat supplied a better-balanced protein mixture than the basal ration of grains and oil meal, and also more of the diet accessories needed for rapid growth. These accessories are also apparently present in alfalfa.

Corn silage for beef cattle, by J. L. Tormey.—In six trials, each of which lasted 90 days, a total of 63 2-year-old steers were fed. In these trials the addition of silage to rations of concentrates and either alfalfa or clover hay decreased the amounts of concentrates required per pound gain, but increased the roughage requirement. In all cases the addition of the silage lessened the feed cost per pound of gain and reduced the necessary margin, although a heavy concentrate allowance with less silage produced more rapid gains. For fattening 2-year-old steers an average daily ration throughout the feeding period of 20 lbs. of corn silage, 5 lbs. of clover, alfalfa, or mixed hay, 12 lbs. of shelied corn, and 2 lbs. of cotton-seed meal, or amounts of other protein-rich concentrates furnishing an equal amount of digestible protein, is recommended.

In one of the trials steers fed an average ration of 37.6 lbs. silage, 3.1 lbs. clover hay, and only 7 lbs. concentrates (3.1 lbs. corn, 2.7 lbs. cotton-seed meal

and 1.2 lbs. wheat bran) per head daily gained 2.36 lbs. per head daily. A lot fed 13.5 lbs. concentrates (9 lbs. corn, 2 lbs. cotton-seed meal, and 2.5 lbs. wheat bran), with 28.8 lbs. silage and 3.2 lbs. clover hay, gained 2.59 lbs. per head daily. However, the feed cost of the gains of these steers fed the heavier concentrate allowance was 16 per cent higher and the margin necessary in feeding was 31 cts. greater.

Studies in animal breeding (Wisconsin Sta. Bul. 268 (1916), pp. 9, 10).—Studies on the effect of such poisons as lead on the germ cells of the male showed the same deleterious results as were obtained the year before (E. S. R., 33, p. 368).

Work on the inheritance of epilepsy in guinea pigs has shown that this disease is inheritable and follows Mendel's law.

In a study, carried on by H. L. Ibsen, of the growth of guinea pigs in embryo and after birth it has been observed that the weights of the different embryos in a litter show that the first and last embryos are invariably larger than those in the middle of the same horn of the uterus. It is popularly believed that the "titman" or runt of a litter of pigs is the last one to be born, but this observation would seem to indicate that such is not the case, as the smaller embryos are always found in the middle of the row of young in the uterus.

In experimental work on the influence of close inbreeding, carried on by J. G. Halpin, it is reported that with Rhode Island Reds results of a detrimental character are beginning to be observed, that the closely inbred stock takes longer to hatch and frequently does not produce so strong chicks as those from the control pens.

The influence of sires on production, C. C. Hayden (Mo. Bul. Ohio Sta., 1 (1916), No. 7, pp. 211-215, figs. 2).—Partial records were kept of the results of the use of various bulls in the station dairy herd. The first bull used on the first group of cows came from a dam which had a good official record, and the granddam on the sire's side had a record of large production. His sire was more noted as a show-ring favorite than as a sire of producing daughters. The results showed an average gain of the daughters over their dams of 1,902 lbs. of milk and 60 lbs. of fat for the first year, and an average yearly difference of 1,176 lbs. of milk and 42 lbs. of fat for all periods.

A second bull was selected for this group, the price paid being about twice that for the first bull. He had better records of production back of him, and the results justified the greater expenditure. The gain over the original dams by the use of this bull was for the first calf 4,074 lbs. of milk and 156 lbs. of fat, and for one year of all lactation periods, 4,207 lbs. of milk and 153 lbs. of fat. The gain over the daughters of the previous bull was for the first year only 2,172 lbs. of milk and 96 lbs. of fat, and for one year of each lactation period, 3,031 lbs, of milk and 111 lbs. of fat.

The first bull used on the second group was selected from one of the best herds in Ohio, though his sire and dam had no official records. A decrease of 687 lbs. of milk and 39 lbs. of fat showed that the use of this sire greatly reduced the productive capacity. His double daughters produced 3.520 lbs. of milk and 202 lbs. of fat, or a decrease of 521 lbs. of milk; nd 32 lbs. of fat below their dams.

The daughters of a second bull used on this group show an increase over the daughters of the first bull of 752 lbs. of milk and 32 lbs. of fat per year. For the first lactation period only they show an increase of 1,205 lbs. of milk and 49 lbs. of fat, indicating that they will be far superior to the daughters of the first bull when they are mature. At the time this second bull was purchased his ancestry had no official records, but his dam was said to be a heavy persistent milker and his sire was imported.

Sheep-breeding investigations, R. H. Williams and W. S. Cunningham (Arizona Sta. Rpt. 1915, pp. 554-560).—In continuation of work previously noted (E. S. R., 33, p. 73), it is reported that the Tunis sheep continued to prove themselves vigorous breeders and produce early active lambs with a marked ability to withstand heat. Their greatest fault is that the wool is very coarse, with loose crimp and too much hair, or "kemp."

Hampshire, Shropshire, Oxford, and Dorset breeds have been used to improve the mutton characteristics of the lambs, and have proved valuable for this purpose in the order named. Oxford and Dorset breeds have been eliminated because of the high rate of mortality among the lambs. More recently it has been decided to limit the Shropshire blood because of the smaller size, inferior mutton form, and lower percentage of black faces in their lambs than in those of the Hampshire crosses. Unfortunately, the Hampshire crosses are inferior in wool, having a short staple and light fleeces. The weight and quality of wool of the native sheep, which are of Merino foundation, have not been much improved by the above process.

It is thought that the ideal valley sheep must have a somewhat open fleece, while the range sheep may have a denser and longer fleece, due to their grazing in higher altitudes.

Of the breeds used the Tunis and Hampshire have brought about the greatest improvement. Lambs showing a high proportion of Tunis blood have been active, alert, and hardy, but have given poor quality of wool and are of only fair mutton conformation. The Tunis-native cross has usually resulted in tan-colored face and legs, although many mottled and white faces are found. The wool from this cross is usually of medium staple, good length, and density, but contains too much kemp. The Hampshire blood has been excellent in improving the mutton form, increasing the size, and stamping black faces on their crosses. A table is given showing the weights at different ages and the average weights of fleece for the more desirable crosses.

Data kept for three years indicate that lambs born early in the year usually reach a greater weight at six months than those dropped later. The average weight of lambs born in January was greater than that of any other month; February lambs more than March; March lambs more than April, and April lambs more than May. There was difference of 17.21 lbs. between the average weight of May lambs and those born in February. There is a general tendency for the earliest lambs to reach a larger average weight, due to the fact that there are few or no small lambs.

There has been found to be a great difference in the fineness and denseness of the wool fibers in the various crosses, and certain crosses have been more efficient than others in eliminating the characteristic Tunis hair, or kemp, from the wool. The Hampshire and Shropshire blood have aided materially in improving this fault, the former being of the greatest service.

In this study it has been noted that there is a close correlation between the fineness and the denseness of wool. In every case where a fleece is reasonably fine it is also fairly dense.

Maintenance rations for breeding flocks of mutton and wool sheep, B. O. Severson (*Pennsylvania Sta. Rpt. 1914, pp. 84-117*).—Continuing previous work (E. S. R., 34, p. 171), the four lots of ewes were fed during the 216 days beginning April 19. During the summer months all of the breeding ewes with their lambs were placed on the same pasture. The lambs were allowed to suckle their dams until 16 weeks of age, and during this time they were allowed to consume as much grain as they would eat. After weaning, the ewes were placed on another pasture with no grain and the lambs were continued on

the same pasture and fed a grain ration consisting of shelled corn, oats, wheat bran, and linseed meal, 5:3:2:1. From September 12 to November 5, 978 lbs. of the same grain mixture was fed the 38 ewes.

The average weights of the ewes during the summer months were greater for the two lots of sheep (lots 1 and 3) in which silage had been fed as the sole roughage during the preceding winter. During the entire period the average increase in weight of each ewe in lot 1 was 28.946 lbs., in lot 2, 32.138 lbs., in lot 3, 13.752 lbs., and in lot 4, 15.307 lbs. The Shropshire ewes (lots 1 and 2) thus gained practically twice as much as the Delaine-Merino ewes (lots 3 and 4). It is estimated that the average cost of keeping each ewe during the 216 days was \$2 per head, no credit being given for the value of manure produced while on pasture or the improvement that the sheep brought about by destroying the weeds.

From April 19 to August 9, the Shropshire lambs (lots 1 and 2) made average daily gains per head of 0.573 and 0.484 lb., while the Delaine-Merino lambs (lots 3 and 4) made average daily gains of 0.288 and 0.36 lb. per head. The total cost of feed was \$5.52 for 25 lambs for a period of 112 days.

During a second winter period of 154 days four lots of 10 ewes each were fed. Lots 1 and 3, consisting respectively of Shropshire and Delaine-Merino ewes of breeding age, were fed a roughage ration composed of corn silage supplemented with cotton-seed meal, and a grain mixture composed of shelled corn, oats, bran, and linseed meal, 5:3:2:1, this mixture being fed at such times and in such amounts as were sufficient to keep the ewes in good breeding condition. Lots 2 and 4, Shropshire ewes and Delaine-Merino, respectively, were fed a roughage ration composed of corn silage and alfalfa hay, together with a grain ration as in lots 1 and 3.

During the first four weeks all lots made good gains. The second period of four weeks gave good gains to lots 2 and 4, but only 0.366 lb. per head in lot 1 and a loss of 0.5 lb. per head in lot 3. All lots lost weight during the third four-week period. Comparing lots 1 and 2, the average weight during the winter was greatest in lot 2. The same correlation in average weight existed in lots 3 and 4. These results are the reverse of those secured during the first winter's investigation (E. S. R., 34, p. 171). During the winter period the average loss per ewe in lot 1 was 20.044 lbs. and 5.209 lbs. in lot 2. The Delaine-Merino ewe gained in weight during the winter, lot 3 gaining 1,953 lbs. per head, and lot 4, 17.431 lbs.

The average amount of air-dry matter consumed per head by the Shropshire ewes maintained on corn silage as a sole roughage was 1.922 lbs., while lot 2 averaged 2.651 lbs., lot 3, 1.655 lbs., and lot 4, 2.336 lbs. Comparing the Shropshires in lot 1 with the Delaine-Merino in lot 3, the latter consumed 0.267 lb. less per head and 0.197 lb. more per 100 lbs. live weight during the winter. The Delaine-Merino ewes in lot 4 consumed 0.335 lb. of air-dry matter more per 100 lbs. live weight and 0.315 lb. less per head than the Shropshire ewes of lot 2. The daily cost of maintaining the breeding ewe was 1.522 cts. in lot 1, 2.248 cts. in lot 2, 1.317 cts. in lot 3, and 1.851 cts. in lot 4. The amount of wool produced was slightly greater in lots 1 and 3 than in lots 2 and 4. No effect of the ration fed could be detected from the market classification.

The Shropshire ewes in lot 1 that yeaned averaged 3.5 lbs. less in weight than those of lot 2. Their lambs averaged 0.9 lb. more per head than those of lot 2, but the mortality of both ewes and lambs was greater in lot 1, indicating that the ration possessing corn silage as a sole roughage for Shropshire ewes did not prove satisfactory in this experiment. The pregnant Delaine-Merino ewes in lot 3 averaged in weight 9.6 lbs. less than the ewes of lot 4

that yeaned. The lambs also averaged less in weight at birth in lot 3 than in lot 4, were less active, and had a greater mortality.

A comparison of the Shropshires with the Delaine-Merinos showed their respective average weight to have been 150.5 and 102.9 lbs. At birth the Shropshire lambs average 7.93 lbs. per head and the Delaine-Merino lambs 6.89 lbs. The Shropshire ram lambs averaged 8.27 lbs. and the ewe lambs, 7.28 lbs., while the Delaine-Merino ram lambs averaged 7.1 lbs. and the ewe lambs, 6.64 lbs.

The Shropshire ewes averaged 141.6 lbs. per head at the end of four weeks, after yeaning, a loss of 10.9 lbs. per head. The Delaine-Merino ewes averaged 104 lbs. per head, an average loss of 1.4 lbs. per head during this period. The Shropshire lambs averaged 21.5 lbs. at the end of four weeks, an average gain of 13 lbs. per head, while the Delaine-Merino lambs averaged 20.4 lbs. per head, an average gain of 12.9 lbs. per head. Comparing lots 1 and 3 with lots 2 and 4, respectively, practically the same gains in live weight of lambs were made.

In summarizing, it is concluded that the two winter periods show that a ration composed of corn silage as a sole roughage supplemented with cottonseed meal for every 25 lbs. of corn silage fed is unsatisfactory for pregnant ewes, even when supplemented by a good grain mixture. Lambs dropped by ewes of the mutton and wool types, fed a ration composed of corn silage supplemented by cotton-seed meal, as compared with ewes of the same types fed a roughage ration composed of corn silage and alfalfa hay, are heavier, weaker, less active at birth, and have a greater mortality. Breeding ewes fed a ration composed of corn silage supplemented by cotton-seed meal were less active and showed lower vitality during the latter stages of pregnancy than ewes fed corn silage and alfalfa hay as roughages. Lambs raised by breeding ewes of both breeds fed corn silage as a sole roughage and cotton-seed meal as a supplement made satisfactory gains and matured into good vigorous lambs. Corn silage and alfalfa hay proved to be a satisfactory roughage when supplemented by a grain mixture composed of shelled corn, oats, wheat bran, and linseed meal, 5:3:2:1, for maintaining pregnant ewes in vigorous condition for yeaning. The cost of feeds consumed by lot 1 during the winter of 1911-12 was \$3.19 per ewe, and in 1912-13, \$2.38; for lot 2 during the winter of 1911-12 \$4.11 per ewe, and in 1912-13, \$3.46; for lot 3 during the winter of 1911-12. \$2.74, and in 1912-13, \$2.03; and for lot 4 during the winter of 1911-12, \$3.78, and in 912-13, \$2.85. The value of fleeces per head was \$1.767 in 1912 and \$1.968 in 1913 for lot 1; \$1.591 in 1912 and \$2.025 in 1913 for lot 2; \$3.02 in 1912 and \$2.882 in 1913 for lot 3; and \$2.731 in 1912 and \$2.795 in 1913 for lot 4.

The cost of maintaining Shropshire breeding ewes was greater than the cost of maintaining Delaine-Merino ewes, and slightly greater on a live-weight basis. Delaine-Merino lambs made less rapid gains than Shropshire lambs. Delaine-Merino ewes were observed to be more easily afflicted by "foul foot," due to damp weather, than Shropshire ewes. Wintering pregnant ewes in an open shed was conducive to the health and thrift of the ewes and lambs. Such quarters, however, should have a southern exposure, a dry bed, and a well-drained and spacious yard.

Hog and sheep pasturing demonstrations, R. W. Allen (*Oregon Sta., Rpt. Hood River Sta., 1915, pp. 27, 28*).—Thirteen head of 73.5-lb. pigs were put on a 3-acre tract of clover in the spring. Without supplementary feed, 0.57 lb. per hog per day was made for 31 days. During the succeeding 30 days they were also fed rolled barley at the rate of 0.5 lb. per hog per day, and an aver-

age daily gain of 0.44 lb. per hog was made. During the 56 succeeding days the animals were run on the same clover, and in addition pastured off 4 acres of field peas grown in an adjoining tract. On this ration they made an average daily gain of 0.77 lb. per hog.

It is estimated that for the entire period \$11.35 per acre was realized from the clover, and \$6.80 per acre from the peas for a 52-day period. In addition to these pigs 20 head of small pigs were also run on both the clover and pea pasture.

For the purpose of determining the amount of gain that sheep will make and with what degree of success they can be kept in bearing orchards, 8 ewes with their lambs were kept on 1 acre of clover that had reached an average height of 10 in. for three weeks and fed it down closely. The following two weeks they fed down an additional acre, the decrease in time necessary being principally due to the greater amount of forage consumed by the lambs. During 52 days the lambs gained 63.2 lbs. each, and the ewes 3 lbs. each, making a total gain of 534 lbs. for the 16 head. From the amount of forage consumed by these animals it appears that 16 head of sheep, half of which are mature, can be carried on 3 acres of clover in bearing orchards.

Dry lot versus pasture crops for growing and fattening pigs for market, W. H. Tomhave and H. H. Havner (*Pennsylvania Sta. Rpt. 1914, pp. 122-128, pls. 5*).—Four 1-acre plats were sown for a rotation of pasture crops consisting of oats and Canadian field peas; field corn drilled; and rape. A lot of 19 9-week-old pigs was pastured on these plats and a similar lot pastured on a dry lot of ½ acre. The pigs on the dry lot were fed a ration of corn meal and tankage 8:1, and those on pasture corn meal and takage 12:1.

The pigs on forage-crop pasture made larger and more economical gains than those in the dry lot. The cost of grain per pound of gain varied from 4.72 to 5.96 cts, in the pasture lot, and from 6.08 to 7.6 cts, in the dry lot. The rate of gain varied from 0.804 to 1.57 lbs, per pig daily in the pasture lot, and from 0.724 to 1.378 lbs, in the dry lot, due to the two systems of management. The pigs on pasture had a higher degree of finish and were more thrifty than those in the dry lot. The use of a rotation of pasture crops proved more profitable than dry-lot feeding.

[Feeding experiments with hogs], W. H. Tomhave (Pennsylvania Sta. Rpt. 1914, p. 82).—In an experiment to determine the value of pasture for growing pigs as compared to dry-lot feeding two lots of weanling pigs were fed as follows: Lot 1, a grain ration of corn meal and tankage, 12:1, in addition to pasture; lot 2, corn meal and tankage, 8:1. The pigs on the pasture made greater daily gains at smaller expense than did those in the dry lot, and they also showed greater thrift.

In a second experiment one lot of 10 shotes was fattened in a dry lot and fed ear corn and 0.25 lb. of tankage. Another lot was given access to standing field corn, and in addition received 0.25 lb. of tankage per head daily. The pigs made an average daily gain of 1.45 and 1.74 lbs. per head, respectively, gaining 11.6 and 12.3 lbs. per bushel of corn consumed, and returning 86.2 and 93.5 cts. per bushel of corn consumed.

Fattening pigs for market, W. H. Tomhave and H. H. Havner (*Pennsylvania Sta. Rpt. 1914, pp. 117-121, pls. 5*).—Four lots of three 138-lb. pigs each were fed for 84 days as follows: Lot 1, corn meal and tankage, 10:1; lot 2, shelled corn and tankage, 10.1; lot 3, buttermilk and corn meal, 1:1. and lot 4, wheat middlings and corn meal, 1:1. These lots made average daily gains of 1.723, 1.567, 1.82, and 1,146 lbs. per head, consuming 3.746, 4.025, 3.367, and 4.7 lbs. of concentrates per pound of gain, costing 1.559, 1.415, 1.5, and 1.424 cts. per

pound of feed consumed, and realizing a total profit per lot of \$14.15, \$13.44, \$15.50, and \$6.94 for the respective lots.

Feeding and management of hogs, J. I. Thompson (California Sta. Circ. 151 (1916), pp. 16, fig. 1).—This circular treats of the breeding, feeding, care, and management of hogs under California conditions, and of the butchering, curing, and keeping of pork.

Hens confined as compared with hens having access to open yard, M. C. KILPATRICK and D. E. WARNER (Pennsylvania Sta. Rpt. 1914, pp. 121, 122).—In an experiment to determine the relation between the number of eggs laid, the amount of feed consumed, and the physical condition of each flock, two lots of 40 White Leghorn hens each were fed, lot 1 being confined and lot 2 having the use of a yard.

At the end of the first 13 weeks the fowls in pen 2 had laid 466 eggs, whereas those in pen 1 had laid only 179. During the second 13 weeks pen 2 laid 1,285 eggs and pen 1, 1,221. During the third 13 weeks pen 2 laid 2,079 eggs and pen 1, 1,589. During the last 13 weeks pen 2 laid 1,525 eggs and pen 1, 1,483.

It is concluded that in order to obtain the best results in egg production it is a decided advantage to allow the flock of hens the use of a yard where they may have room to exercise and secure green feed at certain seasons of the year. There seemed to be, however, a period, from about January to April, when the egg yield from both pens ran about parallel, and when the egg yield from the pen of fowls which had the use of the yard did not indicate that it is necessary for the hens to be out of doors during the winter months.

There was apparently little difference in the amount of feed (concentrates) consumed by each pen, but the results show that the lot which laid the largest number of eggs consumed a little more feed than the other lot. The hens in pen 2 consumed more feed in the first and third periods, and the fowls of both pens ate the most feed at the time when their egg production was the highest. There was no great difference in the physical condition of the fowls of the two lots. In the lot confined, however, the hens seemed to have more completely molted at the end of the first year's work than the lot which had the use of the run.

Ostrich investigations, R. H. WILLIAMS and W. S. CUNNINGHAM (Arizona Sta. Rpt. 1915, pp. 560-562).—A distinct difference was noted in the general appearance of eggs laid by hens of different breeds. Observations during the past year indicated no appreciable difference in the number of eggs laid by the South African and Nubian hens, the average number of eggs laid by the South African hens being 20, the Nubian hens 26.5, and the crossbreeds 23.33. More variation was noted between hens of the same breed than the average of different breeds.

It is possible that the South African hens laid smaller eggs than those of the Nubian breeds, but the crossbred hens laid the largest eggs, averaging 1,616.36 gm. The variation, however, between the average weight of eggs laid by the different hens was great. Thus it is noted that the South African hens laid eggs that weighed from 1,279.6 to 5,110.7 gm., and eggs from the four hens of this breed averaged 1,444.03 gm. The crossbred hens laid eggs that averaged 172.6 gm, heavier than the South African and 27.7 gm, heavier than the Nubian hens.

Similar conclusions may be made with regard to the effect of breed upon the width and length of the eggs. The South African hens laid eggs that were rather short in length and round in appearance, while the crossbred and Nubian hens laid eggs that were larger, of about the same diameter, but greater in length. There seems to be a striking correlation throughout between the weight,

length, and width of eggs, and breed characteristics seem to be significant, although not definitely proved.

It has been shown that ostriches are similar to poultry in that hens beginning to lay early in the season are usually the best layers. The four hens that began to lay in January averaged 36 eggs during the season, and produced 72 per cent of the eggs laid during the year, while only 28 per cent came from the other five hens. The average number of eggs laid by hens beginning to lay in February was 21, in March, 11, and in April, 8.

## DAIRY FARMING-DAIRYING.

Influence of environment and breeding in increasing dairy production, H. H. Kilde and A. C. McCandlish (*Iowa Sta. Bul. 165 (1916*), pp. 383-402, figs. 29).—In this investigation it was attempted to determine the influence of pure-bred dairy sires in increasing the production from a foundation of scrub cows as well as the effect of improved feeding and management. In order that other influencing factors might be brought to a minimum, scrub cows from an isolated region of Arkansas were selected for the basis of this work in 1907. The work is still in progress and the data presented in this publication are in the form of a preliminary report, taking all records completed up to the end of 1915.

The animals purchased were inferior individuals, being rather small, of very limited abdominal, udder, and vein capacity, and very unprepossessing so far as quality and top lines were concerned. The scrub cows and their calves were given the same care, feed, and shelter as the pure-bred dairy cattle in the herd. This environment has remained fairly constant during the eight years' work. Pure-bred sires of the Guernsey, Holstein, and Jersey breeds were used on these scrub cows and all heifer calves grown under the same conditions as the pure-bred calves on the farm. Heifers by pure-bred sires were bred to other pure-bred sires of the same breed and the heifer calves resulting from this union were also kept for dairy purposes.

The results of the eight years' work as given are summarized as follows: The scrub cows that came to the station when young (four years old) increased in production rapidly and steadily up to the fourth lactation period after reaching the station, when they produced 59 per cent more milk and 54 per cent more fat than during the first period. The scrub cows that came to the station advanced in age did not increase in production after the first year. However, it can not be said that their production was not greater than it had been under their original environment.

The scrub heifers developed at the station averaged 13 per cent more milk and 12 per cent more fat than did the scrub cows that came to the station when four years old or over. The daughters of all except one pure-bred bull have proved to be much better producers, as 2- and 3-year-olds, than their dams as mature cows. The average of all the records made by first generation heifers by a pure-bred Holstein sire show an increase of 2,314.5 lbs., or 71 per cent, in milk and 67.15 lbs., or 42 per cent, in fat, at an average age of three and a half years, over the records of their scrub dams at an average age of six years. The average record of the one first generation Jersey grade that has freshened was 205.6 lbs., or 6 per cent, more milk and 32.9 lbs., or 20 per cent, more fat, at an average age of two and a half years, than the record of her scrub dam at an average age of seven years.

The greatest increase shown by any of the first generation grades was by the second Guernsey bull used. This heifer as a 2-year-old produced 3,451 lbs., or 131 per cent, more milk and 179.22 lbs., or 136 per cent, more fat than the

average record of her scrub dam reared at the station. However, the average records at an average age of three years made by the first generation grades by the first Guernsey sire used were not quite equal to those of their mature dams, and variation in the ability of sires to transmit dairy qualities is deemed a factor to be considered in selecting a pure-bred bull to head a scrub or common herd, as well as for a high grade or pure-bred herd.

In persistency of milk production the grades were intermediate between the scrub and the pure-bred cows in the herd. The first generation grades were much superior to their dams in dairy conformation. Many of the first generation grades showed the characteristic color of their sire's breed; however, in the case of the Holsteins this was not so pronounced until the second generation. There was no appreciable difference between the scrub and grade calves so far as coefficient of digestion is concerned, but the grades had a greater capacity for handling concentrates than had the scrubs.

Silage alone, compared with silage and hay, as roughage for dairy cows, H. P. Davis (*Pennsylvania Sta. Rpt. 1914*, pp. 173-182).—Two lots of five cows each were fed for three periods of four weeks each. Lot 1 received silage alone for roughage during periods 1 and 3 and mixed hay and silage during period 2, and lot 2 received hay and silage during periods 1 and 3 and silage alone during period 2.

The milk yield decreased with both systems of roughage, but the decrease was less with silage and hay. When silage and hay for roughage followed silage alone there was a slight increase in milk yield over the initial production. Except in one instance there was a decrease each period. When the cows received hay they consumed practically the same amount of silage as when no hay was included in the ration. Both lots consumed an excess of protein and net energy above that necessary for maintenence and milk production when based on Eckles' standard. There were no apparent undesirable physical effects from the feeding of silage alone for roughage with the grains used. There was very at the difference in the cost of the two rations or in the feed cost of milk and milk fat. No perceptible difference was observed in the health of the two lots.

The effect of open-shed housing as compared with the closed stable for milch cows, H. P. Davis (*Pennsylvania Sta. Rpt. 1914, pp. 183-226, pls. 3*).—Continuing work previously reported (E. S. R., 34, p. 182) the results of three years' studies on the effect of open-shed housing and closed stable are given. Two lots of cows were treated alike in every respect except that of housing, lot 1 being kept outside and lot 2 inside.

From the data presented it appears that cows kept under an open shed have keener appetites and consume somewhat more roughage than those kept in stables. There was sufficient protein consumed, when either Armsby's, Van Norman's, or Eckles' standard was considered, to meet the requirements for milk and to maintain the animals. Figured on Eckles' standard there was a slight excess of energy consumed above maintenance and milk production the first two years, and a small deficiency the last year. When computed on Armsby's and Van Norman's standards there was a deficiency in energy consumed for maintenance and milk production each year, except for lot 1 the second year.

The milk yield of the outside lot for the three years was 35,723.8 lbs. and for the inside lot 35,322.3 lbs. It decreased more rapidly each winter for the outside than for the inside lot. Sudden drops in atmospheric temperature caused decreases in milk yield for both lots, the outside lot having a slightly greater decrease. More bedding was required outside, but less labor was necessary to keep the animals clean. Both lots finished each winter's trial in good health,

with the exception of one cow which reacted to the tuberculin test in April, 1914. She had shown no reaction in two previous tests. The hair of the animals kept outside was longer and coarser the first two winters. The third winter this was noticeable in only one animal.

Studies on the market milk of Iowa, B. W. Hammer and A. J. Hauser (Iowa Sta. Bul. 164 (1916), pp. 311-380).—In these studies samples of milk, cream, both table and whipping, and buttermilk were examined. The milk and cream samples were scored according to the score cards adopted by the U. S. Department of Agriculture, while the whipping cream was scored according to the cream score card, with the exception that 30 per cent fat was considered perfect and one point was deducted for each half per cent below this. The buttermilk was examined for flavor, fat, and acidity only. The samples were collected in twelve cities of the State of various sizes.

It was found that some of the market milk and cream of Iowa contains excessive numbers of bacteria. In some cities the average bacterial content of the pasteurized product exceeds that of the raw, although most frequently that of the raw is the greater. Some of the milk and cream sold is very poor in flavor, while some is very satisfactory. Only a small percentage of the samples examined were low in the amount of fat or solids-not-fat. Large amounts of sediment are not uncommon, while some samples show only insignificant amounts of sediment. Excessive amounts of acid are sometimes found in both milk and cream. From the results of the investigation it is concluded that the presence of colon bacteria is a rather unsatisfactory basis for judging the sanitary quality of a sample of milk or cream.

A considerable amount of bulk milk is still sold in Iowa. Quart and pint bottles of milk and half-pint bottles of cream commonly showed considerable variations in the amounts of material contained. It is deemed reasonable when buying quarts to expect an amount not over 2 per cent low, when buying pints to expect an amount not over 3 per cent low, and when buying half pints to expect an amount not over 4 per cent low.

A proposed score card for bacteria in pasteurized milk is given.

A study of the manufacture of dairy butter, E. L. Anthony (Pennsylvania Sta. Rpt. 1914, pp. 163-173, pls. 8).—An experiment was conducted to determine the variations between the different styles of common farm churns as to the percentage of moisture and salt left in the finished butter, as well as the length of time of churning, the percentage of fot left in the buttermilk, and the average rise of temperature of the buttermilk during churning. The types of churn used were a 15-gal. barrel churn, 12-gal. swing churn, and a combined churn and worker. The average moisture content of the butter from the respective churns was 12.39, 13.5, and 13.6 per cent; the average salt content, 4, 3.8, and 2.45 per cent; the time required for churning, 40, 47, and 29 minutes; the rise of the temperature in churning, 6.3, 7, and 5° F.; and the average fat content of the buttermilk, 0.19, 0.229, and 0.18 per cent.

The results of further studies indicate that by properly regulating the churning factors the percentage of moisture can be materially raised without affecting the uniformity. In order to secure a high moisture content it is found better to stop churning while the butter is still in small granules. The studies also showed that with the common hand worker moisture is generally lost as the working progresses, while by working the butter in the combined churn the moisture content increases after a certain amount of working.

Overripened cream did not produce butter of so good quality as cream that was less ripe. In view of those studies it is recommended that cream be ripened to not more than 0.5 per cent acid, and that as low as from 0.3 to 0.4 per cent is advisable under average farm conditions. Three methods (a)

holding cream below 45° until enough had been secured for churning, then raising the temperature to 75° and ripening overnight or till 0.5 per cent of acid had developed, (b) ripening the first gathering at 75° until 0.35 per cent of acid had developed, then cooling to 55°, adding subsequent gatherings, and churning without further ripening, and (c) adding a quart of good buttermilk to the first gathering adding each day's gathering, holding at cellar temperature until enough had been secured for churning, and ripening if necessary by warming to 75° until 0.5 per cent of said acid had developed, were all found to give butter of a quality superior to that secured by the method now commonly used, viz, that of holding cream at cellar temperature without trying to control the bacteria which produce the flavors in cream. With average farm cream handled under proper conditions a uniform butter of good quality and score could be produced. The method of holding cream at 75° until 0.3 per cent acid is developed and then churning it made butter with better keeping qualities. Butter not worked enough was gritty and mottled, but too much working destroyed the grain and resulted in a greasy product.

[Dairy investigations] (Wisconsin Sta. Bul. 268 (1916), pp. 34-36).—Tentative results of a study of Wisconsin butter marketing conditions conducted by B. H. Hibbard and A. Hobson in cooperation with the Office of Markets and Rural Organization of the U. S. Department of Agriculture indicate that the quality of butter as it is now handled does not result in a material difference in price. The uniformity in product adherent to the package and the advertising given to the product appear to be factors of no small moment in the determination of price.

In experiments by J. L. Sammis an effort has been made to extend the use of the method of pasteurizing milk for cheese-making purposes by the use of the "holding" instead of the "flash" method of heating. The tentative results secured indicate that a product of good quality can be made, and also point to the possible elimination of the method of acidulating the milk for the restoration of its coagulating power with rennet, as has been found necessary by the use of the "flash" method of heating. The process has proved a success in commercial practice.

Experiments have been made with reference to the application of the method to the manufacture of brick cheese. An improvement in the flavor of the product was secured, the gas-producing bacteria were eliminated, and an increase in yield was obtained.

Making butter and cheese on the farm, C. Larsen and V. R. Jones (South Dakota Sta. Bul. 164 (1916), pp. 344-374, figs. 18).—This bulletin gives detailed methods for making butter and cheese on the farm. Among the kinds of cheese discussed are Cheddar, cottage, Neufchâtel, pimento, cream, olive cream, and club cheese.

## VETERINARY MEDICINE.

Infection and immunity, C. E. Simon (*Philadelphia: Lea & Febiger*, 1915, 3. cd., rev. and enl., pp. X+17-351, pls. 12, flgs. 21).—In this new edition of the work previously noted (E. S. R., 30, p. 878), the recent advances in the study of Abderhalden's protective ferments and the associated technique have received detailed consideration. The section on the Wassermann reaction has been almost entirely rewritten. The manner in which danger from anaphylactic shock during serum treatment may be reduced to a minimum has also received attention. Emphasis has been given to the important observation of Schick and his collaborators that it is possible to recognize those individuals whose blood normally contains a quantity of diphtheria antitoxin sufficient for protective purposes by the aid of an allergic skin reaction.

A bibliography is appended to each chapter and, although not considered complete, represents those papers on which the volume as a whole is based.

International catalogue of scientific literature. R—Bacteriology. QR—Serum physiology (Internat. Cat. Sci. Lit., 11 (1915), pp. VIII+583+148+27).—The eleventh annual issue of this catalogue (E. S. R., 32, p. 578), which contains schedules and indexes in four languages and an author and a subject catalogue. The subjects catalogued include general and special bacteriology, parasitic protozoology, and serum physiology.

Histological researches on the behavior of the blood platelets in anaphylaxis, U. Pardi (Arch. Ital. Biol., 64 (1915), No. 1, pp. 89-96, pls. 2).—From the studies reported the author concludes that the anaphylactic poison provokes the rapid formation of a thrombus of the platelets in the lungs and liver. There is a close relation between this condition and the morbid phenomena. Such a condition in the pulmonary vessels clearly explains the respiratory symptoms and pulmonary emphysema noted in anaphylactic shock.

The relative value of certain methods for the production of antisheep amboceptor, Rose Schweitzer and V. Stevens (Collected Studies Bur. Lab. Dept. Health N. Y. City, 8 (1914-15), pp. 433-435).—After investigating a number of procedures the following is deemed the most preferable, since it results in the lowest percentage of mortality and in the most potent immune serum: Inoculation of 50 per cent suspension in a series of increasing doses, beginning with 0.25 cc. and increasing 0.25 cc. every third day.

The proteins and antitoxin in the serum of goats immunized against diphtheria, E. J. Banzhaf and L. W. Famulener (Collected Studies Bur. Lab. Dept. Health N. Y. City, 8 (1914-15), pp. 208-212).—The unit relationship per gram of protein of the pseudoglobulin and euglobulin remained practically the same during the course of immunization.

The diphtheroid bacillus of Preisz-Nocard from equine, bovine, and ovine abscesses.—Ulcerative lymphangitis and caseous lymphadenitis, I. C. Hall and R. V. Stone (Jour. Infect. Diseases, 18 (1916), No. 2, pp. 195-208).—The authors report having isolated the Preisz-Nocard bacillus from characteristic abscesses in eleven horses and one calf.

"The etiology of the lesions from which it was obtained is identical with that of caseous lymphadenitis of sheep, and the disease in horses known as ulcerative lymphangitis should be differentiated by laboratory diagnosis from farcy, epizootic lymphangitis, and sporotrichosis, all of which have a mutual resemblance clinically. Bacillus Preisz-Nocard is a diphtheroid bacillus, presenting interesting characteristics as follows: (1) The production of orchitis in guinea pigs, as well as suppurative processes generally throughout the lymphatics; (2) the hemolysis of blood agar plates not containing an excess of fermentable carbohydrate; and (3) the elaboration of a soluble toxin, resembling but not identical with that of diphtheria, yet being neutralized partly by diphtheria antitoxin. This apparent partial neutralization suggests the existence of group reactions among soluble bacterial toxins, analogous to the group reaction of precipitins and agglutinins.

"We again draw attention to the uncertainty of experimental orchitis in guinea pigs as a certain test for glanders, and emphasize the necessity of microscopic and cultural examination of pus from such lesions for diagnostic purposes."

Vaccinoprophylaxis and vaccinotherapeutics of glandular diseases by means of a new antistreptococcus vaccine with sensitized virus, M. CARPANO (Mod. Zooiatro, Parte Sci., 26 (1915), No. 9, pp. 353-379; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1662, 1663).—In order to eliminate the susceptibility of treated animals to diseases

due to streptococci during the negative phase after treatment with a "polyvalent antistreptococcus serum" and vaccines now in use, the author has prepared a new polyvalent antistreptococcus vaccine with sensitized virus. The vaccine is obtained from several strains of sensitized streptococci, which are subsequently allowed to sterilize themselves or are killed at low temperatures. The method of preparation is described in detail.

Experimental results submitted show that horses stand small and moderate doses very well which cause no perceptible general reaction when injected subcutaneously. The local reactions are restricted to an edema which afterward hardens and is reabsorbed without forming an abscess. A general effect which may last several days and is undoubtedly due to the absorption and action of the endotoxins produced by the streptococci is manifested after the injection of large doses (50 cc.). For horses of average size the most suitable dose was found to be 25 cc. An active immunity sets in immediately after the injection and is very complete and lasting.

The vaccine also appears to possess undoubted therapeutic properties. This action, though limited, indirectly insures that the vaccine when used for prophylactic purposes will not produce any negative phase. It can therefore be used to advantage in cases of adenitis as well as in suspected infections.

Nitric acid compared with tincture of iodin in the cauterization of wounds infected with rabies virus, D. W. Poor (Collected Studies Bur. Lab. Dept. Health N. Y. City, 8 (1914–15), pp. 111, 112).—Results obtained from experiments on three series of eight guinea pigs each show that 75 per cent of the control animals died after an average incubation of 143 days. Of the animals cauterized with nitric acid only 37.5 per cent died, indicating a saving of 37.5 per cent by means of the acid. Two of the pigs in this group which died of rabies showed an average incubation of 22.5 days, a lapse of time that would permit of a course of Pasteur treatment with a subsequent interval of two weeks for the full development of immunity. Pigs which had their wounds treated with tincture of iodin showed a mortality of 100 per cent. Seven of the animals had an average incubation of 185 days, and one an incubation period of 29 days.

The practical significance of these results is indicated.

Further studies of biological methods for the diagnosis of tuberculosis, J. Bronfenbrenner, M. H. Kahn, J. Rockman, and M. Kahn (*Arch. Int. Med.*, 17 (1916), No. 4, pp. 492-508).—From a further study of the value of biological methods of diagnosis of tuberculosis the authors conclude that "different samples of tuberculin of Besredka, though apparently identical in the mode of their preparation, may differ among themselves in their specific values.

"The most striking variation is in the amount of lipins contained in tuberculin. It is necessary to free each sample of tuberculin of all its lipin fraction before using such tuberculin for the complement deviation test. The lipins may be extracted by fat solvents, but the easiest method was found to be that of separation of the protein fraction by precipitation. Precipitation of the antigenic fraction of tuberculin also offers the possibility of using a standard number of units of antigen and thus eliminating variations due to the quantitative, differences in specific properties of different samples of tuberculin, without increasing the chance of obtaining lipotropic reactions.

"It seems, however, that different samples of tuberculin may vary also qualitatively. The variation rests apparently on the fact of the existence of strain specificity in the antibody. The existence of strain specificity in tuberculosis may explain why the results obtained by different investigators in the complement-deviation test for diagnosis of tuberculosis vary so much.

"The tuberculin of Besredka seems to give the best results in diagnosis by the complement-deviation test. Even though the test is positive in a certain number of clinically nontuberculous cases, the reaction seems to be specific. In at least 87 per cent of such cases the fixation was obtained also with one or more preparations of tuberculins other than that of Besredka."

A bibliography of 47 references to the literature cited is included. See also a previous note by Craig (E. S. R., 35, p. 180).

Report on tuberculin tests, L. Cobbett and A. S. Griffith (Roy. Com. Tuberculosis, Final Rpt., II, App., Sup. Vol., 1913, pp. 148, figs. 101).—This supplemental volume reports the results of tuberculin tests on the ox, pig, goat, horse, rhesus monkey, chimpanzee, baboon, mangabey monkey, lemur, dog, cat, rabbit, and fowl. The effect of the successive injections of tuberculin into tuberculous animals, the action of homologous and heterologous tuberculin, the effects of tuberculin when given by channels other than that usually employed, the more immediate effects of injecting living tubercle bacilli into tuberculous animals when compared with those produced by tuberculin, and the ophthalmic tuberculin test were also studied and the results reported.

The experimental results are reported in tabular form, and the febrile conditions of the animals after inoculation are presented graphically. See also a previous note (E. S. R., 35, p. 75).

The characteristics of tubercle bacilli in human bone and joint tuberculosis, A. Eastwood and F. Griffith (Jour. Hyg. [Cambridge], 15 (1916), No. 2. pp. 257-309).—The results of an investigation of 261 cases are summarized in the following table:

Age period.	Number of cases.	Human.	Bovine.	Atypical.
0-5	47 108 62 15 29	31 75 52 12 26	14 31 7 3	2 2 3 3
10-16. 16-25. Over 25.				

Types of tubercle bacilli at different age periods.

The percentage of bovine cases for all ages from this series is thus 21.1; for cases under ten years, 29; and for cases over ten years, 9.4.

Clinical data and bacteriological results of the cases are reported in detailed tabular form, together with the results and post-mortem findings of inoculation experiments on rabbits with viruses of "human" and "bovine" types of bacilli obtained from the organisms isolated from some of the cases.

The types of tubercle bacilli occurring in tuberculosis of the human genitourinary tract, A. Eastwood and F. Griffith (Jour. Hyg. [Cambridge], 15 (1916), No. 2, pp. 310-314).—In an examination of 17 cases the "human" type of bacillus was obtained in 14 instances and the "bovine" in 3. The 3 "bovine" cases were affections of the kidney in persons aged, respectively, 25, 19, and 20 years.

The clinical data and bacteriological results of the cases examined are reported in detailed tabular form.

Avian tuberculosis, C. H. Higgins and A. B. Wickware (Canada Dept. Agr., Health Anim. Branch Bul. 18 (1915), pp. 10, pl. 1, figs. 3).—This bulletin briefly discusses the prevalence, symptoms, and course of the disease; post-mortem findings; transmission of tuberculosis from birds to man; and prevention and treatment.

The authors have observed and demonstrated the presence of the disease in two canaries. Gross lesions were present in nearly every organ and microscopic examination showed great numbers of acid-fast bacilli of the avian type. The disease has also been observed in turkeys in a number of instances,

Investigations to determine the possibility of congenital tuberculosis being present in chicks have been carried on by the authors, but the experiments in this connection have thus far yielded only negative results. The results however, are not considered conclusive.

In an examination of eggs bacilli microscopically indistinguishable from those of tuberculosis were found in about 20 per cent of the eggs examined. Subsequent inoculation of guinea pigs with material from these eggs produced a generalized tuberculous infection from which typical avian cultures were procured.

In experiments with tuberculin as a practical method of diagnosis no marked variation in temperature was observed in four fowls which received 2 cc. of avian tuberculin subcutaneously. In four fowls which were given 1 cc. of concentrated tuberculin intradermally (the thickened skin of the breast) no evidence of any local or thermal reaction was observed. Fowls which received one drop of tuberculin in the eye manifested no evidence of an ophthalmic or a thermal reaction.

Further studies on the nutritive deficiencies of wheat and grain mixtures and the pathological conditions produced in swine by their use, E. B. Harr, W. S. Miller, and E. V. McCollum (Jour. Biol. Chem., 25 (1916), No. 2, pp. 239-259, pls. 5, figs. 9).—The animal (swine) feeding experiments herein reported supply information regarding the rôle played in both animal and human nutrition by toxic materials in apparently normal food products, the results reported being supplementary to those obtained by the authors in earlier work (E. S. R., 35, p. 472). Their conclusions are in part as follows:

"Malnutrition, histologically characterized by nerve degeneration, may result from the absence of certain factors in the diet, as in the case of beriberi. A similar condition may likewise arise from the presence of toxic materials in apparently normal food products and in the presence of all known factors essential for continued growth and well-being.

"With a large mass of wheat in the ration of swine toxicity will follow, even in the presence of all the recognized factors for growth. Only in the presence of very liberal quantities of all these factors can the effect of the toxicity be overcome. This toxicity manifests its action by producing important histological changes in the nervous system of the animal, not unlike those recorded for beri-beri. No one important factor for growth, such as better proteins, salts, or fat-soluble A, appears able to act as a complete corrective for this toxicity.

"It also appears possible to produce similar pathological conditions in swine in the absence of all known toxic material and in the presence of a fair quality of protein, a plentiful supply of fat-soluble A and water-soluble B, but a poor salt mixture, namely, that natural to the grains used."

Studies on the transmission and prevention of cestode infection in chickens, J. E. Gutberlet (Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 2, pp. 218-237).—"The results of these experiments show that the intermediate (cysticercoid) stage of Choanotania infundibuliformis occurs in the common house fly (Musca domestica). The results were obtained by feeding flies on eggs of the tapeworm and raising cysticercoids in a fly; also by feeding chicks on flies and raising the worms in the birds. By morphological comparison of the cysticercoid and an adult they are shown to be identical. Results from experi-

ments by feeding flies on eggs from Davainea cesticillus and D. tetragona were negative,

"The habits of the birds are important factors to be considered in experimental work for life-history studies. Certain insects are found in great numbers around chicken houses and yards and are readily eaten by the birds. Flies are known to contain the larval stage of one species of cestode, and some other species of insects are to be considered as probable intermediate hosts for other species of cestodes.

"The symptoms and effects of the infection from tapeworms vary with individual birds, age of birds, and the degree of infection. Birds infested with worms display an emaciated, unthrifty condition, an unnatural desire for food and water, and a marked diarrhea, with droppings of a characteristic yellowish-brown color.

"The control of tapeworm disease in chickens is in an unsettled condition. Little can be done until more is known concerning life histories of worms. Preventive measures are urged rather than curative measures. Droppings should be cared for and treated with appropriate substances in order to prevent insects from feeding on them or developing in them. Experiments by giving lye with food to infested chickens showed satisfactory results in removing tapeworms.

"The flocks of chickens that were studied showed at times a very heavy infection, and nearly every bird examined harbored one or more species of worms. Five species were found in the chickens at Hardy, Nebr., and three in the birds at the poultry farm at the University of Illinois. The species found in Nebraska are D. cesticillus, D. tetragona, D. echinobothrida, Hymenolepis carioca, and C. infundibuliformis. At the poultry farm of the university the species D. cesticillus, D. echinobothrida, and H. carioca were found."

#### RURAL ENGINEERING.

Annual report of the agricultural engineer during 1914–15, W. M. SCHUTTE (Ann. Rpt. Dept. Agr. Bombay, 1914–15, pp. 72–87).—This is a report of the activities of the agricultural engineer's office, which included experiments on implements and machinery, power, irrigation, water supply, and mechanical cultivation.

Methods of stream gaging, W. S. Pardoe (Engin. News, 75 (1916), No. 19, p. 889).—This is a mathematical analysis of computation methods generally used.

Surface water supply of the Great Basin, 1913 (U. S. Geol. Survey, Water-Supply Paper 360 (1916), pp. 293, pls. 2, flg. 1).—This report, prepared in cooperation with the States of Utah, Nevada, California, Oregon, and Idaho, presents the results of measurements of flow made during 1913 on streams in the Great Salt Lake and Sevier Lake basins, minor basins in Nevada, Humboldt-Carson sink basin, Pyramid and Winnemucca lakes basins, Surprise Valley, and Honey, Warner, Abert, Silver, Malheur, and Harney lakes basins.

Surface water supply of St. Lawrence River basin, 1914, W. G. HOYT, A. H. HORTON, C. C. COVERT, and C. H. PIERCE (U. S. Geol. Survey, Water-Supply Paper 384 (1916), pp. 128+XXIX, pls. 2).—This report, prepared under the direction of N. C. Grover and in cooperation with the States of Minnesota, Wisconsin, New York, and Vermont, contains the results of measurements of flow made in 1914 on streams tributary to Lakes Superior, Michigan, Huron, Erie, and Ontario and to the St. Lawrence River.

Surface water supply of the Lower Mississippi River basin, 1914, N. C. Grover, R. Follansbee, and G. A. Gray (U. S. Geol. Survey, Water-Supply

Paper, 387 (1916), pp. 60+XXXIV, pls. 2).—This report, prepared in cooperation with the States of Colorado and New Mexico, presents the results of measurements of flow made on streams in the Arkansas and Red River basins during 1914.

Surface water supply of New Mexico, 1914, J. A. French (Santa Fe, N. Mex.: State Engin. Dept., 1914, pp. 151, pls. 4).—This report, prepared in cooperation with the U. S. Geological Survey, presents the results of measurements of flow made on streams in the principal river basins of New Mexico in 1914.

Geology and underground water of Luna County, New Mexico, N. H. Darton (U. S. Geol. Survey Bul. 618 (1916), pp. 188, pls. 13, figs. 15).—This is a more complete and detailed report of work previously noted (E. S. R., 32, p. 384).

Geology and ground waters of northeastern Arkansas, L. W. Stephenson and A. F. Crider (U. S. Geol Survey, Water-Supply Paper 399 (1916), pp. 315, pls. 11, figs. 4).—This report describes the physiography and geology of northeastern Arkansas and discusses the occurrence and distribution of surface and ground water by counties. A section, by R. B. Dole, on the chemical character of the surface and ground waters of the region is also included.

Colorado River and its utilization, E. C. La Rue (U. S. Geol. Survey, Water-Supply Paper 395 (1916), pls. 25, figs. 5).—This paper gives the results of measurements of flow made on the Colorado River and its tributaries and deals with the utilization of the water for irrigation and power development purposes.

Physical properties of some toxic solutions, G. B. RIGG, H. L. TRUMBULL, and MATTIE LINCOLN (Bot. Gaz., 61 (1916), No. 5, pp. 408-416).—Experiments on the osmotic pressure and surface tension of (1) water obtained from sphagnum bogs of the Puget Sound region and Alaska, and (2) solutions obtained by allowing rhizomes of Nymphwa polysepala to decay in water are reported.

It was found that "the osmotic pressure of bog water in the samples tested was higher during the rainy season than at the close of the dry season. The osmotic pressure of the waters tested from lakes and springs was lower during the rainy season than at the close of the dry season. There is no indication that either high osmotic pressure or low surface tension is an important factor in the toxicity of bog water or of very dilute solutions resulting from the decay of Nymphæa rhizomes."

Tests of a new process of sewage purification with grease recovery and apparent profit, R. S. Weston (Amer. Jour. Pub. Health, 6 (1916), No. 4, pp. 334-343, fig. 1; abs. in Engin. News, 75 (1916), No. 19, p. 913).—Experiments with Boston sewage conducted by E. S. Dorr and by the Massachusetts Institute of Technology are reported and compared. The process involves the addition of either sulphuric or sulphurous acid to the sewage to precipitate the bulk of the solids in the form of a sludge which can be dried and degreased, the purpose being to produce a greaseless fertilizer and to save the grease.

From the experiments by Dorr it was concluded that each 1,000,000 gal. of sewage would yield 1,361 lbs. of fertilizer base, "which was estimated according to agricultural standards to be worth \$13.59 a ton.

The Massachusetts Institute of Technology experiments verified the results with reference to the amount of sludge obtained from Boston sewage. The results obtained were taken to indicate "that the sludge from the Miles process, although less in bulk than that from the activated sludge process, has a value of more than \$24 per million gallons of sewage."

Irrigation investigations, G. E. P. SMITH and A. L. ENGER (Arizona Sta. Rpt. 1915, pp. 570-577, figs. 2).—The work in irrigation investigations at the station for the year is reviewed. Data on the economics of pump irrigation indicate that "in general, the most advisable practice consists in wells of 600 to 2,000 gal. capacity, pumps of the sizes from 4 to 8 in., 4-cycle oil engines of from 12 to 60 horsepower, and enough farmers cooperating—two,three, or four—to utilize fully the plant 140 hours each week through the good growing months from April to August."

Tests of a 15-in., 5-stage, 110-ft. pump with the bottom of the bowls 28.5 ft. below normal water level are also reported. "The tests show that a very high efficiency can be obtained with this type of pump if the pump is working under its best conditions of head and discharge, but that at other heads or other discharges the efficiency may be low. This emphasizes the importance of knowing the operating conditions in advance and of buying a pump especially designed for those conditions."

The irrigation of sugar cane in Mauritius, F. A. STOCKDALE (Dept. Agr. Mauritius, Gen. Ser., Bul. 6 (1916), [English Ed.], pp. 12, pl. 1, fig. 1).—This pamphlet deals with the scientific principles and the essentials of practice of irrigation with special reference to the irrigation of sugar cane on the island.

The operations of the Royal Commission of Irrigation in the first triennium, O. Bordiga (Atti R. Ist. Incoragg. Napoli, 6. ser., 66 (1915), pp. 1-16).—The first three years' activities of the commission are reported, which deal briefly with defects in the irrigation laws of Italy; irrigability of lands; irrigation economics; and irrigation water, its quality and action on crops and soil.

Annual irrigation revenue report of the Government of Bengal for the year 1914-15 (Ann. Irrig. Rev. Rpt. Bengal, 1914-15, pp. II+71, pl. 1).—This report covers the year 1914-15.

Report of the state drainage commission of Minnesota (*Rpt. State Drain. Com. Minn.*, 1915, pp. 68, pls. 11).—This reports the activities of the state drainage commission of Minnesota and the work and expenditures of the state drainage engineer's office. The text of the laws prescribing the duties and defining the powers of the state drainage commission is also given, together with engineering information regarding drainage areas in Minnesota, evaporation, precipitation, run-off waters and formulas, state ditches, and maximum, minimum, and average discharge of various streams of the State.

Tests show strength of corrugated culvert pipe, G. L. Fowler (Engin. Rec., 73 (1916), No. 21, pp. 668, 669, figs. 4; abs. in Engin. News, 75 (1916), No. 20, p. 958).—Tests under hydrostatic pressure of 12-, 24-, and 48-in. corrugated iron pipes with corrugation depths of  $\frac{1}{2}$  and  $\frac{3}{4}$  in. and uniform pitch of corrugations of  $2\frac{2}{3}$  in., and sand bed tests of the same, are reported. Considering the three variables, diameter of pipe, thickness of metal, and depth of corrugation, the following formula was developed:

$$P = \frac{5,960 \, CT}{2 \left(\frac{D-12}{12}\right)} \left(1 - 0.4 \log \frac{D}{12}\right)$$

where P=collapsing pressure in pounds per square inch, C=corrugation depth in inches, T=thickness of metal in inches, and D=inside diameter in inches.

For sizes from 10 to 24 in., metal thicknesses of from 0.0625 to 0.141 in., and working pressure of half the collapsing strength, the formula was simplified to

working pressure  $=\frac{34,000CT}{D}$  on the assumption that for this range of sizes the collapsing pressure varies inversely as the diameter.

In the sand bed tests it was found that there was arching of the sand under pressure. "It was found that the lateral thrust rose to a maximum under a shallow depth and remained practically constant. With a slightly yielding bottom the sand arched to relieve the bottom of load which was carried by frictional resistance of sand against the box sides. In the main tests, it was found that when the platen was wider than the pipe the pressure was largely supported by the column of sand over the pipe and less by the more yielding sand beyond the pipe walls. Then the load imposed on the pipe was greater than as if considered uniformly distributed by the platen. The results exhibited the conveyance and distribution of sand pressures, but were not considered sufficient to warrant developing a formula for calculating culvert pressures. For instance, it was seen that the top pressure on pipe decreases with a given load placed on increasing depths of sand, but the proportional relations were not disclosed. The lateral pressures were low and no definite ratio was estabhished. The lateral pressure increased rapidly from the top down to a point determined by the angle of repose of the sand and then decreased. . . .

"It is concluded that under the heaviest load that can now be applied to railway ties by any existing locomotive or car, a 24-in. 14-gage pipe with ½-in. depth of corrugation, and under 24-in. cover of dry sand, can not be deflected beyond its elastic properties of complete shape recovery. The 36- and 48-in. culverts are held to be uncrushable under a cover equal to their own diameter. The weight of cover in a wide loose fill or bank is not so well supported as in a ditch, and it was concluded that conditions of unusual severity might be induced which should be provided for by heavier metal."

Experiments on the distribution of vertical pressure in earth, R. B. Fehr (Ann. Rpt. Penn. State Col. 1914, pp. 117-123, pls. 13).—The results of tests with dry sand, silty yellow clay, gravelly silt loam, and brown dry river sand, and on a mixture of these, to determine the distribution of pressure due to a concentrated load through various depths of the soils are graphically reported, together with a description of methods and apparatus used.

"The following depths of sand were tested: 3, 6, 12, 18, 24, 36, 48, and 59 in. For each depth the eccentricity of the load was varied from 0 to 42 in. both right and left. The loads were applied in increments of 1,000 lbs. as indicated by the gage up to the point where the loading strip sank into the sand as fast as the load was applied. As determined from the calibration curve these loads varied from about 600 lbs. to between 2,200 and 6,000 lbs., according to the depth of the sand."

It was found that "there was a very marked change in the percentage of transmission when the eccentricity of the load was equal to the width of the weighing strip and at this point the maximum value was 13 per cent. For greater eccentricities this value was never exceeded. . . . The size of the restricting box does not make any appreciable difference in the results. The maximum bearing power of the sand decreased with the depth of sand. . . . There was a distinct tendency for the percentage of transmission to increase as greater loads were applied."

With the clay loam sand mixture "the method of procedure was exactly the same as in the sand tests except that the eccentricity of the load was varied from 24 in. right to 24 in. left, and back across the soil to the starting point. . . . The depths tested were as follows: 6, 9, 12, 18, 24, and 36 in. . . .

"In practically all cases there was quite a regular increase in the percentages of transmission as the load varied from 600 to 10,000 lbs. per square foot, the maximum loads causing an average increase of 36 per cent in the transmission as produced by the minimum loads. . . . The tests in loam were run in exactly

the same way as those on the clay mixture, but only on 6, 12, 24, and 36-in. depths. . . . As in the case of clay there was quite a regular increase in the percentage of transmission as the loads varied from 500 to 10,000 lbs. per square foot, the average increase from minimum to maximum being 47 per cent."

It is generally concluded that "the percentage of transmission increases with increase of load. For depths of earth greater than 2 ft. the percentage of transmission is always less than 20. For eccentric loads the percentage of transmission is always less than 20 when the loading strip is not over any part of the weighing strip."

Pressure of wet concrete on the sides of column forms, A. B. McDaniel and N. B. Garver (*Engin. News*, 75 (1916), No. 20, pp. 933-936, figs. 5).—Field and laboratory tests made at the University of Illinois are reported.

The laboratory tests were made on 12- and 20-in. square column forms 12 ft. high made of planks, with ship lap joints. The concrete was a 1:2:4 mixture of standard cement, glacial sand, and crushed limestone. The following conclusions were drawn: "The lateral pressure increases with the head up to a certain point, after which the pressure remains nearly constant until the pouring ceases. It is probable that, during the early part of the pouring, the concrete is supported by pressure upon the base of the form, and later a considerable part of the concrete is supported by arch-like action on the sides of the form. In this respect the action of green concrete seems to be similar to that of grain, seeds, clean dry sand, etc., in a bin. The lateral pressure in general corresponds to hydrostatic pressure for wet concrete. The lateral pressure increases with the rate of pouring and the degree of wetness and of the consistency. The lateral pressure is about the same for column forms up to 20 in. square."

The field tests were conducted on a reinforced concrete arch highway bridge. "The tests were made on the spandrel posts of the longer spans. These posts have a cross section of 23 by 30 in. and a maximum height of about 15 ft. They have both vertical and horizontal reinforcing bars." The concrete was a 1:2:4 mixture of cement, sand, and gravel. It was found "that the pressure gradually increases with the head until a maximum is reached, after which the pressure falls off. The height at which this maximum pressure occurs depends upon the consistency of the concrete and upon the rate of pouring. The actual pressures recorded approximate very closely that of a liquid having the same weight as the concrete, or about 145 lbs. per square foot per foot of head.

"The results obtained from the field tests agree closely with those secured from the laboratory tests. Concrete falling against the forms may result in high lateral pressures due to impact. A value of 145 lbs. per square foot [per foot] of height would be a rational value for lateral pressure to use in the design of forms. The results of these tests are not conclusive, but it is believed that they are sufficiently consistent and accurate to furnish lateral-pressure values which may be used as a basis for the design of forms under average working conditions."

Dynamite experiments, B. Bunting (Agr. Bul. Fed. Malay States, 3 (1915), No. 9, pp. 337-341; abs. in U. S. Dept. Com., Com. Rpts., No. 102 (1916), p. 416).—Experiments to test the effect of explosives on the growth of rubber in loam soil overlying a heavy clay are reported.

"Taking the experiments over a period of one year it [was] observed that whereas the control gave an increase of 21.93 in., the dynamite plat gave an increase of 32.14 in. for every 100 in. of the original girth, or an increase over the control of 10.2 per cent. • • •

"Dynamite is unequaled for breaking up hardpan or layers of impervious subsoil, which not only prevent the roots from going down to the subsoil but interfere with the drainage. It is most effective on heavy clay and hard laterite soils and least effective on light or loose soils which offer no resistance to the explosion. It might be profitably employed in holing previous to planting, especially in heavy soils, half a charge of dynamite being sufficient for this purpose. It may be successfully used in breaking up logs and tree stumps infected with termites in rubber clearings. The value of dynamite for cultivation is not doubted, but the high cost of the explosive prevents its more general use."

Stump removal, G. Lundberg (Skogsvårdsför. Tidskr., No. 5 (1915), Sup. 1, pp. 40, figs. 25).—This report deals with stump breaking and removal and describes and illustrates methods and machinery used in this work in Sweden.

The American road, I, II, J. I. Tucker (Norman, Okla.: Author, pts. 1, 1915, pp. 34+[5]; 2, 1916, pp. 35-82+[4], figs. 5).—Questions and texts prepared for the extension division of the University of Oklahoma are given.

Road laws of Ohio (Columbus, Ohio: Bd. Library Comrs. Ohio, 1915, pp. XXXIX+335).—The text of the laws is given in three parts.

Part 1 includes the Cass highway act, which is a codification and revision of the more important road laws that were in force previous to its enactment. Part 2 contains sections of the general code relating to the duties of various county and township officials in connection with roads and the provisions relative to tax levies and the limitation of the tax rate. In many instances citations are given to court decisions. Part 3 presents the law relating to motor vehicles.

Good roads year book, 1915 ([Off.] Good Roads Year Book U. S., 1916, 5. ed., pp. VIII+440).—This is the fifth number of this book (E. S. R., 29, p. 388), containing information regarding road improvements under federal, state, territorial, and local control; historical notes and technical details of road construction and maintenance; and European road systems. Miscellaneous information regarding highway bonds, state geologists, and manufacturers of road machinery and equipment, engineering equipment, and road-building materials is included, together with a bibliography of 249 treatises on road, bridge, and culvert construction and allied subjects.

Proceedings of the Pan-American Road Congress, held at Oakland, California, September, 1915 (*Proc. Pan-Amer. Road Cong.*, 1915, pp. XV+416, pl. 1).—These proceedings contain the following special papers:

The History and Future of Highway Development, by L. W. Page; The Relation of the Road to Rail and Water Transportation, by C. J. Tilden; The Benefits and Burdens of Better Roads, by S. E. Bradt; Road Building in the National Forests, by H. S. Graves; The Essentials of Proper Laws for Highway Work, by E. A. Stevens; Federal Aid to Rural Districts, by C. L. Mac-Kenzie; Proper Road Location, Its Importance and Effects, by W. R. Roy; Road Drainage and Foundations, by G. W. Cooley; Highway Bridges and Structures, by W. S. Gearhart; Highway Indebtedness, Its Limitation and Regulation, by N. P. Lewis; Organization and System in Highway Work, by A. B. Fletcher; The Educational Field for State Highway Departments, by L. S. Smith; Roadway Surfacings, by F. F. Rogers; Resurfacing of Old Roads, by W. D. Uhler; Street Pavements, by C. Hill; System in Highway Accounting, by S. D. Gilbert; Uniformity for Highway Statistics and Data, by H. E. Reed; Engineering Supervision for Highway Work, by P. Hubbard; The Determination of the Justifiable Outlay for Specific Cases of Highway Improvement, by C. Richardson; How to Take the Roads Out of Politics, by R. H. Dana; Convict Labor for Highway Work, by G. P. Coleman; Motor Traffic, Its Development, Trend, and Effects, by A. W. Gould; Equipment for Highway Work, by A. H. Blanchard; Comparisons of Traffic and Their Economic Value, by L. White; Maintenance—Materials and Methods, by A. W. Dean; and Dust Suppression and Street Cleaning, by W. H. Connell.

Grading aggregates for Illinois concrete roads, A. H. Hunter (Concrete [Detroit, Mich.], 8 (1916), No. 5, p. 209).—A table giving the present requirements as to gradation of aggregates for concrete road work in Illinois is given, together with a table of unit costs of several concrete roads built by day labor under the supervision of the Illinois Highway Commission.

Test of Douglas fir bridge stringers, H. B. MacFarland (Bul. Amer. Ry. Engin. Assoc., 17 (1916), No. 184, pt. 2, pp. 281-467, figs. 153; abs. in Engin. and Contract., 45 (1916), No. 19, pp. 427-430, fig. 1; Engin. Rec., 73 (1916), No. 15, p. 479).—Tests of 61 representative Douglas fir stringers in which the stringers were subjected to a process of creosoting involving boiling under vacuum are described. Nine of the specimens were put to special tests after treatment, while 52 stringers were cut in two and comparative tests made of the untreated and treated halves.

"A comparison of the results of the transverse tests, applying loads at the third points, of 7 by 16 in. by 14 ft. span treated and untreated stringers shows that of the 52 representative untreated specimens 16 failed by shear, 29 by tension, 3 by tension and shear, 2 by crushing and tension, 1 by crushing and shear, and 1 by crushing, while the following numbers of treated stringers failed from the causes noted: Thirty-two shear, 14 tension, 4 tension and shear, and 2 crushing and shear. . . . The average elastic limit of the untreated pieces was 4,269 lbs. per square inch as compared to 3,481 lbs. per square inch for the treated stringers. The average modulus of rupture was 5,691 lbs. per square inch for the untreated and 4,680 lbs. per square inch for the treated stringers. The average longitudinal shear for the untreated pieces was 411 lbs. per square inch, which was 78 lbs. per square inch greater than that for the treated specimen.

"Specimens for the compression tests, applying the load parallel to the grain, were 5 by 5 by 12 in. in size. It was found that the maximum load for the untreated pieces was 4,114 lbs. per square inch and 3,869 lbs. per square inch for the treated blocks. Applying the load perpendicular to the grain of 6 by 6 by 30 in. blocks showed that the treated specimens had an average elastic limit of 322 lbs. per square inch, which was 116 lbs. per square inch less than the average for those that were not treated. The average area penetrated by creosote as determined by this test was 20.41 per cent."

The following conclusions were drawn: "Moisture may be successfully removed by boiling under vacuum. Moisture determinations show that, on an average, 35 per cent of the total moisture was removed by the process. The removal of moisture by boiling under vacuum, preliminary to creosoting, decreases the physical strength of the material. The weight of creosote per unit of volume for treated material is dependent on the structure of the specimen. Spring wood offers greater resistance to treatment than summer wood. Special tests of treated stringers indicate that the decrease in physical strength due to treatment is not confined to the area penetrated by creosote. The entire structure is affected. The compressive strength parallel to the grain was decreased 6 per cent. The compressive strength perpendicular to the grain was decreased 26 per cent. Although the average strength of the treated material is appreciably decreased, its stiffness, as measured by the modulus of elasticity, is not affected. In general, the average strength of

Douglas fir bridge stringers, subjected to the boiling-under-vacuum process of creosoting, was five-sixths of its original strength."

Automobile registrations, licenses, and revenues in the United States, 1915 (U. S. Dept. Agr., Office Sec., Circ. 59 (1916), pp. 15, fig. 1).—This bulletin contains tabulated data on the following: Motor-vehicle registrations, licenses, and revenues, 1915; motor-car registrations and gross motor-vehicle revenues, 1913–1915; motor-vehicle registration and license fees in force January 1, 1916; and administrative provisions in force January 1, 1916, affecting motor-vehicle registrations, licenses, and revenues.

"During 1915 the total gross revenues derived from the registration of motor vehicles and the licensing of operators, chauffeurs, dealers, etc., amounted to \$18,245,713.... Of the total revenue collected during 1915 practically 90 per cent was applicable to road work, and of this slightly over 70 per cent was placed more or less directly under the control and supervision of the state highway departments....

"The number of motor vehicles registered under the general designation of automobiles, motor trucks, and commercial vehicles in continental United States during 1915 amounted to a total of 2,445,664. The total road mileage of the United States outside of incorporated towns and cities is approximately 2,375,000 miles. There is, therefore, an average of slightly more than one motor car for each mile of rural public road in the United States."

Prevention of pounding in kerosene engines, J. A. MOYER and J. P. CALDER-wood (Ann. Rpt. Penn. State Col., 1914, pp. 109-117, pls. 10).—Experiments with a 4-cycle hit-and-miss governed oil engine with a cylinder bore of 6.75 in., a 10-in. stroke, and a clearance of 22.9 per cent to determine the cause of pounding and methods for its prevention are reported. The carburetor was an experimental spraying type.

It was found that pounding was increased by increasing the temperature of the gas, increasing the temperature of the jacket water, and increasing the spark advance. Pounding was decreased by increasing the fuel rate and increasing the water injection. "In attempting to draw conclusions from these results it is practically impossible to state whether this pounding was produced by cracking of the heavier hydrocarbons or by high flame propagation, but from a practical point of view the conditions affecting either of these causes are identical, and inasmuch as we can prevent or govern this pounding by the use of water and rich fuel mixtures, meaning a relatively large amount of kerosene used compared with the air, it seems that differentiation as to ultimate cause is not necessary. . . . In using gasoline under conditions of fuel mixture and water temperature similar to those imposed upon kerosene in these tests the pounding and the indicator cards are identical with those of kerosene. These tests show also very clearly that the temperature of the fuel mixture at the firing period is the condition that governs the quality of the pounding."

Directory and specifications of leading makes of trailers (Farm Machinery, No. 1284 (1916), pp. 18, 19).—This list contains the names and specifications of 75 types of trailers of 30 different makes.

Official tests of mechanical cultivation, RINGELMANN (Jour. Agr. Prat., n. ser., 29 (1916), No. 4, pp. 74, 75).—The more important results of tests of several outfits are summarized in the following table.

## Results of mechanical plowing tests.

	Donath of		Average speed per hour.	Area plowed per hour.	Fuel consumption.	
Type of outfit.	Depth of plowing.				Per hour.	Per hectare.
fotor cultivator fotor plow ractor Do	14. 4 15. 0 16. 0 24. 0 15. 8 18. 1 13. 2 12. 3 16. 1 18. 0 14. 2	Meters. 1. 00 . 56 . 96 . 59 . 57 . 59 1. 50 . 99 1. 17 1. 12	Meters. 4,572 4,032 2,952 2,880 2,916 2,952 4,860 1,728 3,132 3,024 2,700 2,880 2,884	Square meters. 3, 165 1, 346 1, 306 2, 043 1, 214 1, 054 1, 540 1, 830 2, 116 2, 052 2, 280 2, 134 2, 110	Kilo- grams. 3.55 5.98 5.42 7.73 5.83 10.42 8.70 4.43 8.12 9.40 10.01 6.89 6.74	Kilo- grams. 11. 2 44. 4 41. 5 37. 8 48. 0 98. 8 56. 5 24. 2 38. 4 45. 8 43. 9 32. 3 31. 9 29. 7

Power required for grinding Pennsylvania and Argentine cereals in flour mills, D. W. Dedrick (Ann. Rpt. Penn. State Col. 1914, pp. 123-133, pls. 10).— Tests to determine the relative amount of power required for grinding winter and spring wheat, the effect on power requirements for the mill occasioned by the conditioning of wheat by the application of moisture to the wheat hull, and the power required for grinding corn and other grains are reported.

It was found "that the winter wheat, conditions being equal, takes considerably less power than spring wheat, and again tempered or conditioned wheat less power than dry. Also that the mills with longer or more roll surface take less power than with shorter or less roll surface, as a comparison of the four tests on spring wheat shows that the five-break, ten-reduction mill takes the least and the three-break, five-reduction mill, the most power. The dry wheat takes more power than the conditioned wheat to which had been added 3 per cent of water and lying six hours to mellow. . . .

"It was found that when the brushes or scrapers were adjusted, as is usual against the rolls to scrape off material adhering to them in crushing, the rolls took on an average 27 per cent more power than when running with the scraper off. However, in grinding with full load this relation would be changed to about 8 per cent of the power to the rolls. . . .

"It required a little over 38 per cent more power to grind the same quantity of Argentine corn in the same time to the same degree of fineness than for the Dent variety. The second grinding took on an average 68 per cent more power than the first grinding. Power for grinding ordinary white corn is practically the same as that for Yellow Dent. . . .

"The graphic chart shows that there were differences in cleaning wheat, also that the corn took less power for cleaning than wheat.... The winter wheat took 50 per cent of the power to the scourer, the spring wheat dampened 47.73 per cent, and the spring wheat dry 45.24 per cent, while the corn took 40.3 per cent....

"In the large class of mills the proportion of roll surface and other machinery per barrel is generally considerably less than that for a small mill, and is owing to a more minute division of and consequently a more equitable distribution of stock throughout the mill. A 25, 50, or 75 barrel mill will use 1.8 to 2 in. per barrel or even more, whereas a 500 or 1,000 barrel mill will use 1.7 to 1.6 in, or even less per barrel and consequently somewhat less

power per barrel, The following formula may be used for determining capacity and power:

$$C = {d \text{ n S l} \atop \text{f b}}$$
;  $h = {1 \atop \text{c}}$  and  $T = C p$  where

C=capacity in barrels; d=diameter of roll, inches; n=3.1416; S=speed of fast roll, revolutions per minute; l=total length of roll surface, inches; f=constant used=109; b=barrel=196 lbs.; h=inches roll per barrel; p=horsepower per barrel, as 0.4 for plain, 0.35 for collar, and 0.26 for ball bearing; T=total horsepower for mill."

Composition of galvanized-wire fencing materials, E. S. Erb and W. Freak (*Pennsylvania Sta. Rpt. 1914*, pp. 377-390, pls. 3).—This article reports studies of the composition of more or less well-known wire fencing materials and of newly purchased portions of the principal commercial brands on sale in Pennsylvania, together with a description of methods of analysis.

Farm buildings, how to build them, W. E. FRUDDEN (Charles City, Iowa: Author, 1916, pp. 63, figs. 159).—This is a booklet of practical information intended for the farmer and rural contractor, covering the construction of general farm barns, hog houses, cribs and granaries, poultry houses, fences, homes, miscellaneous farm buildings, and handy devices.

Community hog houses, J. B. Davidson, J. M. Evvard, and W. G. Kaiser (Iowa Sta. Bul. 166 (1916), pp. 406-458, figs. 42).—This bulletin enumerates the essential features of an ideal hog house and the advantages and disadvantages of the community type of hog house, and describes and illustrates the construction of two successful types of community hog houses, namely, the "Iowa sunlit community hog house" and the "semi-monitor roof house".

The distinguishing features of the Iowa sunlit community hog house are the location of the windows in the roof, thus furnishing direct sunlight to all parts of the house, and low walls used with the idea of reducing cost of construction.

The distinguishing feature of the half-monitor roof hog house is the arrangement and location of the windows. "A row of vertical windows is provided for lighting each of the two rows of pens. The house extends with the long axis east and west, and is not at all adapted to any other direction. When the windows are placed at the right height, direct sunlight will shine into both rows of pens at the same time. If plenty of windows are provided, the pens will be quite thoroughly lighted."

A previous bulletin by Evvard and Davidson dealt with movable hog houses (E. S. R., 32, p. 284).

Water supply for the country home, M. K. SNYDER (Wash. State Col., Dept. Ext. Bul. 11 (1916), pp. 62, figs. 27).—This bulletin deals with the sanitary aspects of farm water supplies, purification of farm water supplies, and small water supply systems.

With reference to source, farm water supplies are divided into rain, surface, spring, and ground waters. The usual precautionary statements regarding the protection of wells and springs are given. With reference to the safe distance from pollution for wells it is stated that "if the earth is reasonably uniform, without any well-defined channels along which the water passes, the safety distance is from 75 to 100 ft. above the source of pollution to from 200 to 250 ft. below the source. If there are well-defined channels in the earth, no distance pelow the source of pollution is safe."

Water purification by mechanical and chemical treatment is discussed and the doubtful utility of small faucet filters pointed out. With reference to small sand filters, it is stated that "the sand layer, at the time of construction, should not be less than about 3 ft. deep and depths greater than 5 ft. are costly

without giving added safety. The water should be kept at a depth of 2 ft. or more over the top of the sand so that the surface of the sand will not be disturbed by any possible currents from the entering water or from other sources. . . . The best results are obtained by using for the filter sand a sand that will pass through a screen having about 20 meshes to the inch, and will not pass a screen having 50 meshes to the inch. . . . The rate of operation should be about 50 gals, per square foot per day." Chemical treatment by use of calcium hypochlorite and quicklime is also described.

The discussion of water supply systems includes descriptions of centrifugal, plunger, and air-lift pumps and hydraulic rams. It is concluded that "if pumping is done by hand from a well of any considerable depth, the cylinder must be of small diameter and the discharge will be correspondingly small. Even when a windmill is used in direct connection with a pump, it is best to use a cylinder of small diameter so that the mill will pump with light winds (8 to 12 miles per hour). But when a gasoline engine or an electric motor is used the power is supplied at a constant rate and the pump should be selected to use this power. This allows the selection of a pump with larger cylinder and consequently less time is required to do the pumping."

Cost data are also included.

House heating, J. L. Mowry (Univ. Minn., Dept. Agr., Ext. Bul. 60 (1916), pp. 15, figs. 21).—This pamphlet deals with the general proposition of house heating and describes the stove, hot-air, hot-water, and combination hot-water and hot-air systems, giving hints on installation and automatic control.

## RURAL ECONOMICS.

Rural economy in New England at the beginning of the nineteenth century, P. W. Bidwell (*Trans. Conn. Acad. Arts and Sci., 20 (1916), pp. 243–399*).—The author has classified the changes in the rural economy in New England into three periods as follows:

"(1) The period of self-sufficient economy, which had existed since the settlement of the country, reaching the highest point of its development at the beginning of the nineteenth century, a period in which the characteristic features of rural economy were the absence of any market for farm produce and the consequent dependence of each town and, to a large extent, of each household, even, on its own resources for the satisfaction of its wants; (2) the period of transition to commercial agriculture, under the stimulus accorded by the rise of manufacturing enterprises in inland towns and villages and the consequent demand for food and raw materials on the part of the newly arisen nonagricultural population, the years included in this period being approximately the two generations from 1810 down to the close of the Civil War; and (3) the period of decadence of New England agriculture, extending from the close of the Civil War to the end of the nineteenth century, a period in which the increasing pressure of Western competition caused the abandonment of large numbers of New England farms and a decline in both the quantity and quality of the rural population."

The author presents a survey of the rural economic conditions in Massachusetts, Connecticut, and Rhode Island at the close of the first period under the following chapter headings: The inland towns and their village settlements, the coast and river towns, commercial relations of southern New England with the Southern States and the West Indies, internal trade and the transportation system, the agricultural industry, and home and community life in the inland town. A brief bibliography is appended.

A rural survey of Morgan County, Missouri, W. L. Nelson and M. W. Witten (Missouri Bd. Agr. Mo. Bul., 14 (1916), No. 2, pp. 51, figs. 35).—This bulletin summarizes replies received from public-school teachers and children, relative to farming conditions within the county, the condition of the rural schools, farmhouses, and the types of farming and of other rural industries.

[Farming and farm labor conditions in North Carolina] (Ann. Rpt. Dept. Labor and Print. N. C., 29 (1915), pp. 16-29).—These pages give by counties the condition of the land, tendencies regarding the size of farms and diversifications, wages paid, the cost of producing the principal farm crops, and the condition of the roads, education, and finances.

List of farms for sale, 1915 (Hartford, Conn.: Bd. Agr., 1915, pp. 157, figs. 17).—This bulletin brings up to date for 1915 the list previously noted (E. S. R., 32, p. 390) of farms for sale in Connecticut.

Farms for sale or rent in New York, 1916, C. W. LARMON (N. Y. Dept. Agr. Bul. 78 (1916), pp. 425-624, pls. 44).—This bulletin brings up to date for 1916 the list previously noted (E. S. R., 33, p. 490).

Pennsylvania farms for sale (*Penn. Dept. Agr. Bul. 273 (1916)*, pp. 106, pl. 1).—This bulletin contains a compilation of the farms in Pennsylvania offered for sale, and gives a detailed description of the land, buildings, water supply, and distances from the railroad station, post office, and churches, together with the price asked.

Statistics and agriculture, R. Kindler (Mitt. Deut. Landw. Gesell., 31 (1916), No. 4, pp. 46-54).—In this article are discussed the various types of statistical reports relating to agriculture, methods of reporting, and the general tendency of agricultural production in Germany as revealed by her agricultural statistics.

The rural life of Japan (*Tokyo*, *Japan: Bur. Local Affairs*, 1914, pp. 111+51, pls. 8).—This book contains a number of typical instances illustrating the industrial and moral spirit of the farming classes and the influence of the authorities and leaders in building up an ideal type of rural people.

Farm contracts between landlord and tenant, W. C. TICHENOR (Lebanon, Ohio: Author, 1916, pp. XII+245).—This book outlines the different types of contracts that are in common practice between landlord and tenant, and the subjects of agreement arising in farm leases and the law pertaining to them. Copies of a number of lease contracts are included.

Amortization methods for farm mortgage loans, L. E. TRUESDELL and C. W. THOMPSON (U. S. Dept. Agr., Office Sec. Circ. 60 (1916), pp. 12).—This circular describes different methods of computing payments of mortgages by the amortization plan. Detailed tables are given showing the amount of payment necessary with the variation in interest and length of time for repayment by the various methods described.

Farm credit problems in Wisconsin (Wisconsin Sta. Bul. 268 (1916), pp. 32-34, fg. 1).—These pages contain a brief statement concerning the farm credit investigations of B. H. Hibbard, the results of which are given in detail in a bulletin previously noted (E. S. R., 32, p. 892).

Annual report on the working of cooperative societies in the Bombay Presidency, 1915 (Ann. Rpt. Work. Coop. Soc. Bombay Pres., 1914-15, pp. 3+71+5).—This report continues data previously noted (E. S. R., 32, p. 593.)

Economic effect of cold storage upon the average price of eggs, B. Groes-BECK and F. G. Urner (New York: Joint Com. Cold Storage Warehousemen and Affiliated Indus. [1916], pp. 10, pl. 1).—The authors have summarized their conclusions as follows:

"The per capita consumption of eggs at New York has increased largely since ample cold storage facilities became available.

"Considering differences in the quality of the eggs quoted there has been no considerable advance in wholesale values of fresh-gathered eggs, either during the season of flush or of short production, in the period 1900–1910 as compared with a similar period before cold storage was available.

"The average prices of fresh gathered and storage eggs taken together were lower during the season of scarcity in the period since cold storage has been available than were the prices for fresh-gathered eggs before cold storage was available, notwithstanding a well-known advance in the prices of nearly all commodities during the decade, beginning 1900.

"Accumulations of eggs in cold storage during the season of excess production are practically exhausted before the next season of flush begins.

"The ability to carry eggs in cold storage from the period of greatest production throughout the later period of shortage greatly increases the opportunity for profitable production without enhancing the average prices and adds to the food supply."

Monthly crop report (U. S. Dept. Agr., Mo. Crop Rpt., 2 (1916), No. 6, pp. 49-60, fig. 1).—This number contains the usual data regarding the range of prices at important markets, average price paid to producer, and estimated farm values on May 15; together with data concerning the acreage in water-melons and cantaloups in 1915 and 1916 and the percentage of the crop harvested in each month, the condition on June 1 of the truck crops and the principal agricultural crops, and the estimated annual supply of potatoes in the United States.

A special report on long-staple cottons is included, indicating that 7.4 per cent of the total crop is of long-staple variety, which in an ordinary season amounts to approximately 825,000 bales. According to this report, of the cotton produced in the principal cotton-producing States, the following percentages of the total are long-staple varieties: Arizona, 90; Mississippi, 23; Missouri, 20; California, 20; Arkansas, 14.4; and Oklahoma, 13.5. There is also included a special article by O. F. Cook on The New Long-Staple Cottons.

A recent statement issued by the U. S. Bureau of the Census regarding the manufacture of wagons and carriages is cited which indicates that the number of carriages manufactured in 1914 was 34 per cent less than in 1909 and the number of wagons 9 per cent less.

A special inquiry regarding the months in which hogs are slaughtered on farms shows that 32.1 per cent are slaughtered in December, 20.3 per cent in January, and 19.5 per cent in November; that is, practically 72 per cent of the hogs slaughtered on farms are slaughtered during these three months.

Acreage and live stock returns of England and Wales (Bd. Agr. and Fisheries [London], Agr. Statis., 50 (1915), No. 1, pp. 75).—This report continues data previously noted (E. S. R., 33, p. 789).

[Agricultural statistics of Hungary] (Ungar. Statis. Jahrb., n. ser., 21 (1913), pp. 73-119).—These pages continue data previously noted (E. S. R., 34, p. 596).

[Agricultural statistics in Switzerland] (Statis. Jahrb. Schweiz, 23 (1914), pp. 54-65).—These pages continue data previously noted (E. S. R., 33, p. 193).

Agricultural statistics of British India (Statis. Abs. Brit. India, 49 (1904-5—1913-14), pp. 126-135).—This report continues data previously noted (E. S. R., 33, p. 295).

Statistical returns of crops in Southern Rhodesia, 1914-15, E. A. Nobbs and B. Haslewood (Rhodesia Agr. Jour., 13 (1916), No. 1, pp. 28-44).—These pages contain a general description of the condition of agriculture in Southern Rhodesia, together with statistical data showing the area under crops, the total yields, the amount of silage, and the area of irrigated lands, with sources of water supply.

### AGRICULTURAL EDUCATION.

Report of committee on graduate work in horticulture, M. J. DORSEY (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 74-87).—This survey of the present status of graduate work in horticulture is divided into three main heads, viz, (1) the teaching and research staff, (2) the material equipment, such as laboratory, library, orchard, etc., and (3) the product, or type of training given.

The staff is discussed from the standpoint of training, freedom of time, and specialization. A table comparing the formal degrees of the horticultural workers of 1915 with those of 1905 shows that there is a noticeable increase in the group of associates in the 10-year period, a relatively large decrease in the number of horticultural workers holding no degree, and in 1915 a relatively larger number of workers with only a bachelor's degree. Another table, comparing the formal degrees of the horticultural staff in 16 of the larger institutions giving graduate work in horticulture with those of the staff in the department of chemistry, calls attention to the larger number of workers in the chemistry group of the rank of instructor and assistant holding advanced degrees, and the larger number of heads of departments with the doctorate degree, suggesting the probable influence of this advanced training upon the standards of undergraduate as well as graduate instruction and departmental leadership. The committee considers specialization as one of the most effective means of increasing efficiency in the staff as well as giving a larger freedom of time. The exchange arrangement between Cornell and Wisconsin universities and the cooperative arrangement between the horticultural department of the West Virginia University and the department of plant physiology of the University of Chicago are mentioned as among significant recent movements toward giving instructors a broader experience and viewpoint.

The investigation of the product, or type of training given, reveals the facts that there are 9 institutions offering work in horticulture leading to the doctor's degree and approximately 20 scheduling work for the master's degree. The time required is uniformly one year's residence or the equivalent for the master's degree. The departments of horticulture offering work for the doctor's degree come under the control, in every case, of well-organized graduate schools, and the standardization of requirements for advanced degrees is well taken care of by other agencies, the uniform requirements for this degree being three years' residence in advanced work, as a minimum while research in one minor in some related field is generally required. At the present time there are registered 10 students for the doctor's degree in horticulture and 77 for the master's degree, exclusive of those at the Pennsylvania, Virginia, Massachusetts, or New Jersey colleges. Graduate courses in pomology are scheduled in 13 institutions, in olericulture in 9, in landscape gardening in 5, in floriculture in 6, and in plant breeding in 8, while 5 list their graduate work under thesis research. In the last five years there have been 84 theses in horticulture submitted, 19 States only being represented. An analysis of the subjects, practically all of which are for the master's degree, shows that 51 could be classified under pomology, 10 under plant breeding, 4 under olericulture, and 1 under landscape gardening. Nearly all of the institutions offering graduate work have assistantships or fellowships, varying in amounts from \$100 to \$1,000 a year, available in the department of horticulture. Extracts from letters are included setting forth the principles involved in residence credit for graduate assistants.

Report of committee on floriculture, E. A. White (*Proc. Soc. Hort. Sci.*, 12 (1915), pp. 111-113).—The committee reports as to (1) the provision of better facilities for teaching floriculture, including new ranges at the Ohio and Indiana universities and the Iowa College, and extensive additions to

glass-house areas for teaching at the Illinois and Cornell universities, (2) the strengthening of courses and the marked improvement in the nature of the work given, and (3) the publication by the chairman of the committee of a text entitled Principles of Floriculture to meet the needs of smaller institutions where only a general course in floriculture is given in connection with other horticultural courses.

In institutions where there are special courses in floriculture the committee considers the lecture system, supplemented by required outside reading, the best method of instruction. It emphasizes the importance of requiring students intending to specialize first to have a knowledge of chemistry, soils, and fertilizers, and also botany in all its phases, especially in plant physiology and pathology. It considers business training an essential and a certain amount of farm practice as leading to greater efficiency, and is of the opinion that practical experience in floriculture can be secured nowhere better than in an up-to-date commercial range under the supervision of a broad-minded practical floriculturist.

Organization and methods for pomology extension work, R. W. Rees (*Proc. Soc. Hort. Sci., 12* (1915), pp. 63-68).—The author outlines the development of pomology extension work and methods that have proved successful at the Massachusetts College. He believes that the "principle of close relationship and mutual understanding between the extension service, the experiment station, and the college is necessary for successful development. All extension work should be outlined in form of definite projects so efforts may be concentrated on the most essential problems. With the rapid development of the agricultural county farm bureaus the extension work in each county should be conducted in cooperation with the agricultural agents. In counties which have a pomologist, the work should be largely carried on by him under general supervision of the extension pomologist at the college."

Agricultural instruction in Prussia, E. VITAL (Wiener Landw. Ztg., 65 (1915), Nos. 93, p. 688; 94, pp. 693, 694).—This is a review of the development and present status of agricultural instruction in Prussia.

Yearbook of the Department of Agriculture, Industries, and Commerce in the Dutch East Indies, 1914 (Jaarb. Dept. Landb. Nijv. en Handel Nederland. Indië, 1914, pp. VI+331, pls. 16).—This is a report of the Department of Agriculture, Industries, and Commerce, including its activities in promoting agricultural instruction and research in 1914, in the Dutch East Indies.

Preliminary suggestions for agriculture, domestic science, and manual training for elementary grades and high schools (Des Moines: Dept. Pub. Instr., 1915, 2. ed., pp. 21).—This bulletin outlines the minimum requirements of the Iowa law as to the amount of agriculture, domestic science, and manual training that must be taught, the grades in which the subjects shall be offered, the teaching force needed, the preparation in these subjects required of teachers, and the special rooms, apparatus, and equipment necessary.

Helps for teachers of agriculture, January-April (Dept. Pub. Instr. [Ind.], Ed. Pubs., Bul. 12 (1915), pp. 30).—This portion of the bulletin outlines the second four months' work in soils and poultry, horticulture and dairying, and animal husbandry and farm crops, continuing previous work (E. S. R., 32, p. 597).

Correspondence courses in agriculture for teachers. Course I, farm plants and soils (Corresp. Courses Teachers [Iowa], Agr. Ext. Dept., Course I, Farm Plants and Soils, Assigns. 5, pp. 21, figs. 15; 6, pp. 23, figs. 8; 7, pp. 24, figs. 4; 8, pp. 22, figs. 7; 9, pp. 23, figs. 4; 10, pp. 24, figs. 4; 11, pp. 24, figs. 8; 12, pp. 24, figs. 9; 13, pp. 24, figs. 9; 14, pp. 24, fig. 1; 15, pp. 28, figs. 14; 16, pp. 35,

figs. 29; 17, pp. 18, fig. 1; 18, pp. 21, fig. 1).—These bulletins comprise lessons, prepared for the purpose of giving teachers in the rural and graded schools of Iowa a sufficient knowledge of agriculture to meet the requirements of the school law and of supplying outlines showing what to teach and how the material can best be presented. The lessons deal with the cultivation, history, distribution, improvement, varieties, etc., of the principal grain crops, the cultivation of potatoes, the home garden, fruit growing, trees on the farm, planning and planting the farmstead, legumes, forage crops, plant diseases and injurious and beneficial insects, weeds, fertilizers, and crop rotations.

Productive farm crops, E. G. Montgomery (Philadelphia and London: J. B. Lippincott Co., 1916, pp. XIX+501, pl. 1, figs. 205).—This book was written to meet the needs of students having some practical knowledge of crop production in agricultural short courses and secondary schools and of beginners in agricultural colleges. Because of its practical nature it may also be used as a handy reference book for farmers. The author has endeavored to develop the fundamental principles of crop production as demonstrated by practical experience, dealing with the classification, origin, distribution, growth, cultivation, insects and diseases, harvesting, and utilization of field crops in general as well as of individual crops. Practical exercises and review questions are included in each chapter. Data as to local weeds, market grades of hay and straw, and grades of grain are appended.

The small grains, M. A. Carleton (New York: The Macmillan Co., 1916, pp. XXXII+699, pl. 1, figs. 183).—This book is intended primarily for instruction in colleges and universities, but is also adapted for use in agricultural short courses, in academies and high schools, and by farmers and general readers. After a brief discussion of the fundamental principles of plant structure and nutrition, as related to cereals, the four principal cereals are treated separately and from the individual plant standpoint as to their origin, characteristics, classification, varieties, selection, and hybridization. Then, to avoid duplication, these cereals are treated together with reference to the further subjects of soil and climatic relations, acclimatization, cultivation, irrigation, weeds, insect and fungus pests, and uses. Buckwheat and rice, being botanically different from the four cereals referred to, are treated separately as to all topics. An extended bibliography is appended.

Corn and cotton, edited by C. A. McMurry (Peabody Col. Bul., 1 (1915), No. 2. pp. 48).—This pamphlet contains studies of the history, production, improvement, and uses of corn and cotton, the marketing and manufacture of the latter, competition in the manufacture of cotton goods, and references to literature on these subjects. The pamphlet is designed for the use of teachers and includes suggestions on methods, but is simple enough to be used by children as a text.

Weeds, L. G. Atherton (Normal Teacher [Madison, S. Dak.], 5 (1915), No. 6, pp. 31, figs. 13).—This is a suggestive outline for the use of teachers in the introduction of the study of weeds in rural and village schools.

Laboratory manual in general microbiology, W. Giltner et al. (New York: John Wiley and Sons, 1916, pp. XVI+418, pl. 1. figs. 97).—This laboratory guide is based on the work of instructors at the Michigan College for over a decade and consists of three parts. The purpose of part 1 is primarily to give a working knowledge of laboratory methods used in the study of microorganisms, molds, yeasts, and bacteria being taken up in the order of their comparative size and studied as to their identification by morphological and cultural methods; part 2 consists of exercises demonstrating the various physiological activities of micro-organisms; and part 3 deals with applied microbiology. An appendix contains an outline for the study of microbiology, data on media, solutions, stains, etc., and a list of text and reference books.

Instructions for collecting and preserving valuable Lepidoptera for scientific purposes, J. Sinclair (Los Angeles, Cal.: Author, 1916, pp. 80, figs. 61).— The instructions, given in simple language and avoiding technical terms, are followed by cuts and descriptions of valuable butterflies and moths, as well as of a number of common ones which are very similar to them in appearance.

Poultry study for schools, J. W. Hungate (Dept. Agr. State Normal School [Cheney, Wash.], Bul. A, No. 5 (1916), pp. 19, figs. 7).—The author discusses the value of poultry study, poultry growing as a school project, teaching poultry raising to school children through clubs, poultry enemies, and the prevention of diseases, and outlines 12 exercises. A list of reference books is added.

Outlines in home economics, Neale S. Knowles (Dept. Pub. Instr. Iowa Circ. 4 (1915), pp. 95, pls. 6, figs. 3).—The author outlines a half-year course, consisting of 90 lessons, in home economics for high schools. Five periods a week are to be devoted to the work, viz, two lecture periods and one sewing period of 45 minutes each, and at least two laboratory periods of 90 minutes each. Lists of individual and class equipment and references to literature are included.

Outline of domestic art work for the high school with bibliography. MARTHA PATTERSON (Ala. Girls Tech. Inst. Bul., n. ser., No. 31 (1915), pp. 34).—These outlines in domestic art work are not intended as a course of study, but simply to furnish classified topics of fundamental work from which courses can be organized. Extended annotated bibliographies on domestic art and domestic science, the latter compiled by Louisa J. Keys, are included, together with lists of illustrative material and its sources.

Home projects for agriculture and home economics, Mrs. E. M. Barrett (Texas Dept. Agr. Bul. 47 [1916], pp. 32).—This bulletin contains programs, rules, and regulations for and contests in a number of home projects, rules of the home credit system, a constitution and by-laws for the junior farmers' institute, and a list of free bulletins to be used in home project work.

Course school-home projects, 1916 (Chicago: Co. Supt. Schools, 1916, pp. 15).—This pamphlet gives general directions for school-home project work, and outlines courses in field and garden, business, cooking and sewing, poultry. music, and cow testing school-home projects for the pupils over 10 years of age in the public schools of Cook County, Ill., all of whom now take a course in school-home projects as a part of their regular school work.

A first book of school gardening, A. Logan (London: Macmillan and Co. Ltd., 1915, pp. VII+151, figs. 58).—The aim of this book is to instruct pupils between the ages of 12 and 16 in the fundamental principles of soil management and plant growth and to provide practical instruction through the school garden. Review questions and practical exercises are added to each chapter.

School gardens (Agr. Gaz. Canada, 3 (1916), No. 2, pp. 158-176, figs. 14).—Brief reports are given on the progress of school and home garden work in the Provinces of Nova Scotia, Quebec, Ontario, Manitoba, Saskatchewan, Alberta, and British Columbia.

School fairs (Agr. Gaz. Canada, 3 (1916), No. 1, pp. 77-88, figs. 3).—This is a series of reports on the progress of the school-fair movement in the Provinces of Nova Scotia, Quebec, Ontario, Manitoba, Saskatchewan, Alberta, and British Columbia.

#### MISCELLANEOUS.

Twenty-sixth Annual Report of Arizona Station, 1915 (Arizona Sta. Rpt. 1915, pp. 505-581, pl. 1, figs. 12).—This contains the organization list, an administrative report by the director on the work and publications of the station, a

financial statement for the fiscal year ended June 30, 1915, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue. A brief report on the work and expenditures of the college of agriculture is appended.

Report of Hawaii Station, 1915 (Hawaii Sta. Rpt. 1915, pp. 73, pls. 9).—This contains the organization list, a summary by the agronomist in charge as to the work of the year, and reports of the departments of horticulture, entomology, chemistry, and agronomy, the extension division, and the Glenwood substation. The experimental work recorded is for the most part abstracted elsewhere in this issue, as is also a special report of horticultural observations in Porto Rico, Cuba, and Florida.

Thirty-eighth Annual Report of North Carolina Station, 1915 (North Carolina Sta. Rpt. 1915, pp. 5-43+111, figs. 23).—This contains the organization list, a report of the director and heads of departments, a financial statement for the fiscal year ended June 30, 1915, and reprints of Bulletins 228-231, previously noted.

Report of the Hood River, Oregon, Branch Experiment Station, 1915 (Oregon Sta., Rpt. Hood River Sta., 1915, pp. 61, pl. 1, figs. 14).—A report is given of the work of the year, the experimental features recorded being for the most part abstracted elsewhere in this issue.

Annual Report of Pennsylvania Station, 1914 (Pennsylvania Sta. Rpt. 1914, pp. 522, pls. 73).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1914, a report of the director on the work and publications of the station during the year, departmental reports, many special articles abstracted elsewhere in this issue, and reprints of Bulletins 128 and 133, previously noted.

Beport of the director, 1915, H. L. Russell (Wisconsin Sta. Bul. 268 (1916), pp. 82, ftgs. 47).—This contains the organization list, a report of the work of the station during the year, portions of which are abstracted elsewhere in this issue, brief summaries of the publications of the year, and a financial statement for the federal funds for the fiscal year ended June 30, 1915.

Monthly Bulletin of the Ohio Agricultural Experiment Station (Mo. Bul. Ohio Sta. 1 (1916), Nos. 6, pp. 161-192, figs. 6; 7, pp. 193-224, figs. 11).—These numbers contain, in addition to several articles abstracted elsewhere in this issue, the following:

No. 6.—Variety v. Simple Rations for Laying Hens, by W. J. Buss, an extract from Bulletin 291 (E. S. R., 35, p. 171); Potato Insurance, by D. C. Babcock; and The Mineral Requirements of the Milch Cow, by E. B. Forbes, an extract from Bulletin 295 (E. S. R., 35, p. 481).

No. 7.—Variety Tests of Wheat, by C. G. Williams, an extract from Bulletin 298 (see p. 534); and Forage Crops for Swine, by W. L. Robison, adapted from Bulletins 242 and 268 (E. S. R., 28, p. 468; 31, p. 868).

In memoriam: Eugene Woldemar Hilgard (Berkeley, Cal.: Univ. Cal. Press. 1916, pp. 50, pls. 2).—This includes the addresses at the memorial services held at the University of California, January 30, 1916; a reprint of an editorial from Experiment Station Record (E. S. R., 34, p. 301); and a bibliography of Dr. Hilgard's publications.

# NOT ES.

Arizona University.—Stanley F. Morse, superintendent of the extension service, has resigned to become superintendent of a large commercial guayule plantation near Tucson.

Delaware College and Station.—M. L. Nichols has been appointed assistant professor of agronomy and assistant agronomist, vice W. A. Lintner whose resignation has been previously noted.

Georgia Station.—The building of two additional offices and laboratories to house the agronomist and assistant chemist has been authorized. The work is to be begun at once, as well as other improvements in the buildings and grounds.

Director R. J. H. DeLoach resigned November 1 to organize and direct a bureau of research and education connected with a commercial concern in Chicago. James D. Price, State Commissioner of Agriculture, has been appointed director beginning January 1, 1917. H. P. Stuckey will be acting director until that time.

Idaho University and Station.—Two new silos have been completed for testing new crops in feeding cattle and sheep, making five in use. In addition, 13 wood stave silos of  $\frac{5}{4}$  ton capacity are to be devoted to a study of the fermentation processes of silage and of the use of crops other than corn.

Julius E. Nordby has been appointed instructor in animal husbandry and farm superintendent.

Illinois University and Station.—W. I. Brockson has been appointed assistant in crop production.

Purdue University and Station.—R. S. Stephenson has been appointed instructor in animal husbandry and W. B. Krueck and J. B. Markey assistants in animal husbandry in the college of agriculture, and George Cross assistant in animal husbandry in the station. Charles S. Brewster has been appointed instructor in poultry husbandry. P. S. Richey has succeeded P. E. Thompson, resigned, as assistant in animal husbandry.

Kentucky University and Station.—Dr. J. H. Kastle, dean of the college of agriculture and director of the station, died September 24 after a brief lilness.

Dr. Kastle was born January 25, 1864, at Lexington, Ky., and was graduated from the Kentucky State College in 1884. He received the master's degree two years later from the same institution, and in 1888 that of Ph. D. from Johns Hopkins University. He then returned to Lexington as professor of chemistry, serving in this capacity for 17 years. In 1905 he became chief of the division of chemistry in the Hygienic Laboratory of the U. S. Public Health and Marine Hospital Service, and from 1909 to 1911 served as professor of chemistry in the University of Virginia.

Dr. Kastle was appointed research chemist in the Kentucky Station in 1911, and upon the death of Dean Scovell the following year succeeded him as dean and director. He was a member of the American Chemical Society, the Society of Biological Chemists, the American Physiological Society, and the Society of Chemical Industry, and the author of a long list of publications, mainly in biological and physiological chemistry. When taken sick he was preparing a paper on The Relations of the Experiment Station to Regulatory Work for

the November meeting of the Association of American Agricultural Colleges and Experiment Stations. He was a man of broad vision, marked originality, and clear thinking, and had rendered distinguished service in the fields of research, education, and administration.

George Roberts, head of the department of agronomy, has been appointed acting dean of the college of agriculture and Dr. A. M. Peter acting director of the station.

The department of home economics was separated in September from the college of agriculture as the college of home economics, with Mary E. Sweeny as dean. James Wright Wesson has been appointed assistant in agricultural economics and G. M. Roach inspector in the food and drug department, both appointments taking effect in September.

Missouri Station.—F. L. Bentley has resigned as assistant in animal husbandry to become instructor in animal husbandry at the Pennsylvania College, and has been succeeded by C. W. Sheppard, a 1916 graduate of the college of agriculture.

Nebraska University and Station.—H. E. Vasey, assistant professor of agricultural botany and assistant agricultural botanist, resigned September 1 to become instructor in botany at the Colorado College and assistant botanist in that station.

New Hampshire College.—J. M. Fuller, head of the dairy department of the Oklahoma College and Station, has been appointed professor of dairying, vice F. Rasmussen, resigned to accept a similar position at the Pennsylvania College. Miss Helen Knowlton, of Cornell University, has been appointed professor of home economics and dean of women.

Ohio State University and Station.—William R. Lazenby, associated with the university since 1881 and one of the pioneer educators in horticulture, died September 15, at the age of 66 years. Professor Lazenby was graduated from Cornell University in 1874 and served there as instructor in horticulture and botany until 1878, and as assistant professor until 1881. At Ohio he was professor of botany and horticulture until 1892, then professor of horticulture and forestry until 1909, and since that date professor of forestry.

Professor Lazenby was also one of the founders of the Ohio Station, serving as its first director from 1882 to 1886, and then as vice director until his removal to Wooster in 1888. He was a member of a large number of scientific organizations, among them the American Association for the Advancement of Science, of which he was a fellow and vice-president in 1896; the Society for the Promotion of Agricultural Science, of which he was secretary from 1886 to 1891 and president from 1895 to 1897; the American Forestry Association; and the American Pomological Society, of which he had been vice-president for several years.

Arthur Huisken has been appointed assistant in soils in the station.

Porto Rico Insular Station,—R. C. Rose has been appointed assistant pathologist beginning September 14.

Vermont University.—M. C. Wilson has resigned as farm management demonstrator of New Hampshire and Vermont to become state leader of county agents in New Hampshire. He has been succeeded by Walter G. Tubbs, a 1916 graduate of Cornell University, who will give his entire time to work in Vermont.

Virginia Truck Station.—J. T. Rosa, instructor in truck crops at the Iowa College, has been appointed assistant horticulturist beginning October 1.

Honduras Experimental Station.—A tract of land owned by the State on the Carretara del Sur, about five miles from Tegucigalpa, is being developed for

experimental purposes. The buildings are being remodeled and it is hoped eventually to maintain a complete experiment station and agricultural school. The work at present under way is largely of a preliminary nature with various crops.

Federal Agricultural Legislation.—In addition to the legislation already noted (E. S. R., 35, pp. 101, 200, and 301) a number of other provisions of agricultural and educational interest were adopted at the opening session of the Sixty-fourth Congress.

The act making appropriations for the support of the army establishes a council of National Defense consisting of the Secretaries of War, Navy, Interior, Agriculture, Commerce, and Labor. This council is to supervise and direct investigations and make recommendations, not only as to purely military measures but as to the increase of domestic production of articles and materials essential to the support of armies and of the people during an interruption of foreign commerce and similar matters. It is also to nominate to the President for his appointment an advisory commission of not more than seven persons, each of whom has special knowledge of some industry, public utility, or the development of some national resource. An appropriation of \$200,000 is provided for experimental work undertaken by the council, the advisory commission, or subordinate bodies, for carrying on the work provided.

A section in the National Defense Act of June 3, 1916, provides that soldiers in active service shall hereafter be given opportunity to receive instruction along vocational lines. Civilian teachers may be employed to aid the army officers in giving this instruction, which may include training in agriculture.

Under a provision in the Indian appropriation act, a farmer or expert farmer appointed in the Indian Service after January 1, 1917, and receiving at least \$50 per month, must procure certificates of competency showing that he is a farmer of actual experience and qualified to instruct others in the art of practical agriculture. These certificates are to be issued by the president or dean of the agricultural college of the State in which his services are to be rendered or by the corresponding official of the college in an adjoining State.

The Postmaster General is authorized in the appropriation act for the support of his Department to conduct experiments in three or more communities for the purpose of determining the most practical means of extending the operations of the parcel post in promoting the marketing of products and furthering direct transactions between producers and consumers. An appropriation of \$10,000 is made for this purpose.

A law which establishes standards for the so-called Climax baskets for grapes and other fruits and vegetables and for other types of baskets and containers used for small fruits, berries, and vegetables becomes effective November 1, 1917. Standards of 2, 4, and 12 quarts dry measure are provided for the Climax or "grape" baskets, while other containers are restricted in size to ½ pint, 1 pint, 1 quart, and multiples of 1 quart dry measure. Penalties are prescribed for shipments in interstate commerce which do not conform to these requirements. The Secretary of Agriculture is to establish rules and regulations and to examine containers to determine their compliance with the act.

A standard "large barrel" of 280 pounds net and a "small barrel" of 180 pounds net are established for lime. All lime handled in interstate commerce in barrels must be packed in barrels of these sizes or a fractional part of the small barrel. Rules and regulations are to be prescribed by the Bureau of Standards and approved by the Secretary of Commerce. Penalties are provided for violations, beginning January 1, 1917.

Military Legislation Affecting the Land-grant Colleges.—Under the National Defense Act, the President is authorized to establish and maintain reserve officers' training corps at certain civil educational institutions. Universities and colleges requiring four years of collegiate study for a degree and at which instruction in military tactics is provided under the Morrill Act are grouped under what is known as the senior division of this corps, and each state institution may constitute one or more units of the corps if enrolling under military instruction at least 100 physically fit male students.

The Secretary of War is authorized to prescribe a course of theoretical and practical training for the units of the corps, this to include senior instruction and an average of at least three hours per week per year for the entire course. Provision is made whereby additional officers, noncommissioned officers, and enlisted men may be detailed from the regular army for service at these institutions, animals, arms, uniforms, equipment, and transportation may be supplied as needed, and field camps may be maintained.

Members of the corps who have completed two academic years of service and care to continue the course may be supplied by the United States with commutation of subsistence for the remainder of their course. Graduates up to a total of 50,000, who agree to serve at least ten years as reserve officers, may be so appointed, and any reserve officer thus appointed may be commissioned as a temporary second lieutenant of the regular army for not to exceed six months with pay of \$100 per month and the usual allowances. Graduates between 21 and 27 years of age who, prior to the passage of the act, have received the requisite training may also be appointed temporary second lieutenants and reserve officers.

Another law increases the number of cadets at the U. S. Military Academy. This law provides that 20 cadets are hereafter to be appointed by the President from the honor graduates of educational institutions having officers of the regular army detailed as professors of military science and tactics under the existing law.

A third act provides for the issue of Government supplies to these institutions for the establishment and maintenance of military instruction camps.

National Research Council.—Following a request from President Wilson, the National Academy of Sciences has organized a National Research Council. The purpose in view is stated to be to bring "into cooperation existing governmental, educational, industrial, and other research organizations, with the object of encouraging the investigation of natural phenomena, the increased use of scientific research in the development of American industries, the employment of scientific methods in strengthening the national defense, and such other applications of science as will promote the national security and welfare."

The membership is to include American investigators and engineers, representing the army and navy, the various scientific bureaus of the Departments and the Smithsonian Institution, educational institutions and research endowments, and the research divisions of industrial and manufacturing establishments. Dr. George E. Hale, director of the Mt. Wilson Solar Observatory, has been chosen chairman, and Dr. Raymond Pearl, of the Maine Experiment Station, a member of the executive committee. Committees have also been appointed on research in educational institutions, the promotion of industrial research, and a national census of research.

Agricultural Education and the European War.—According to a statement in the London Times, Mr. F. D. Acland, secretary of the British Board of Agriculture and Fisheries, recently stated in the House of Commons that the scheme of agricultural education had been retarded by the war, but that the popularity of agricultural education had undoubtedly increased and that

there had been real progress in the use made by farmers of the facilities offered. He "sincerely believed that no previous expenditure of money had helped us in this war more than that which had been spent in agricultural education."

Necrology.—Dr. Albert J. Cook, State Horticultural Commissioner of California since 1911, died September 29 at the age of 74 years. Dr. Cook was an early graduate of the Michigan Agricultural College, receiving the bachelor's degree in 1862 and the master's degree in 1864, as well as that of doctor of science in 1905. He also studied at Harvard University in 1867 and 1868.

Dr. Cook began his long career at the Michigan College in 1867 as instructor in mathematics. From 1868 to 1893 he was professor of zoology and entomology, as well as curator of the museum from 1875 to 1893 and entomologist in the Michigan Station from 1888 to 1891. He was professor of biology in Pomona College from 1893 to 1911. He had also been actively engaged in farmers' institute work in both Michigan and California and in the formation of organizations of citrus growers. He was an early experimenter with insecticides, notably kerosene emulsion in 1877 and the use of arsenites for the control of the codling moth in 1880, and the author of a number of works on bee keeping and other agricultural topics.

Prof. J. A. Portchinsky, the distinguished Russian entomologist died May 21 at the age of 68 years. From 1874 to 1894, Professor Portchinsky was scientific secretary to the Russian Entomological Society, and since 1894 chief of the entomological bureau of the Ministry of Agriculture and chief editor of its memoirs. He was the author of 24 memoirs, besides a large number of other scientific contributions. He was also the Russian reviewer of the *Review of Applied Entomology*. He had traveled extensively over Russia, Caucasia, and Turkestan, and collected a mass of materials on the biology of insects.

Foster E. L. Beal, assistant biologist of the U. S. Department of Agriculture from 1891 to 1901 and subsequently economic ornithologist of the Bureau of Biological Survey, died October 1 at the age of 76 years. Professor Beal was a native of Massachusetts and a graduate of the Massachusetts Institute of Technology in 1871. He had specialized in economic ornithology and was the author of numerous publications on the subject.

New Journals.—Verslagen en Mededeelingen van de Directie van dem Landbouw is being published by the Department of Agriculture, Industry, and Commerce of the Netherlands. The initial number contains a history of the appropriations for agriculture in the Netherlands since 1798, an account of the Netherlands cattle trade with foreign countries, a report on agriculture in Great Britain and Ireland and their trade in agricultural products, and a list of the publications of the department from 1904 to 1915.

Boletim Fluminense de Agricultura e Industria is being published by the State of Rio de Janeiro, Brazil, as a means of bringing agricultural information more directly to the attention of farmers. The principal article in the initial number deals with millet.

# EXPERIMENT STATION RECORD.

Vol. 35.

NOVEMBER, 1916.

No. 7.

Nothing in recent years has so emphasized and impressed the real importance of agriculture and agricultural institutions as the war in Europe. It has demonstrated dependence upon this art and has raised it to a preeminent position in the welfare of the country. Ordinarily accepted without much thought or realization by the great body of people, it has suddenly sprung into an importance second only to that of the military activities. It has become, indeed, a recognized field of war service and one of the chief elements in the national defense. Its response, and the resourcefulness and practical value which its institutions have shown, have brought the present position of agriculture close home to the people as never before on so broad a scale.

The problem of maintaining, and in some cases increasing, the production of food for man and beast has been one of the large and difficult ones in the countries at war. It has taxed their skill and organization, and their ability to cooperate in the common good. With thousands of acres devastated, relations with other countries interrupted, and with a vast army of the farmers and laborers on whom production ordinarily rests suddenly become dependent on the labor of others, the necessity of cultivating all available land and making the soil yield its full return became a national concern in all the countries. It inspired unusual measures for stimulating and assisting those who were left on the land, and led to appeals for agricultural workers second only to those for men to fight.

The way in which this extraordinary demand has been met has furnished a new realization of the great advances in every branch of farming. It has entitled agriculture to a regard and consideration which it has not always enjoyed before. If it has not actually raised it to a new position in the lives of nations, intelligent understanding of its position has been greatly broadened.

And along with the rest, this supreme test has furnished an impressive illustration of the great share which agricultural investigation, education, and various forms of instruction have had in placing agriculture on a higher plane of efficiency and in making it more resourceful and adequate. The response of agriculture is in

no small measure a reflection of the steady work of various classes of agricultural institutions and organizations, which has been going on quietly and often with meager support or understanding. The measure of strength of these agencies, and the extent to which there has been some form of agricultural organization to assist, has been a large factor in meeting the unusual situation.

The first efforts in the various countries centered largely on providing the machinery for gathering in and saving the crops, and in this the assistance of the military was furnished to a limited degree. But as time went on the necessity became apparent of providing for the continuance of agriculture on the highest possible plane, of keeping up the fertility of the land, of preventing the depletion of live stock, of avoiding waste of all kinds, and often of discovering and utilizing new sources of supplies. Organized effort was therefore enlarged and increasing latitude extended in the temporary use of soldiers.

The attitude of cooperation between the military and civil authorities is well illustrated by the instructions of the French Minister of Agriculture in transferring to district commanders the assignment of soldiers to agricultural duties. He said: "The regular, prompt, and (as far as possible) complete execution of agricultural work constitutes one of the essential elements of national resistance and consequently one of the principal forces of success. The full use of the soil must be obtained at all costs, equally with the supply of men and material to the army, or the supply of labor to factories engaged in national defense." Soldiers were classified on the basis of farm experience, and opportunity given them to offer themselves for temporary work in the fields. In order to avoid unfavorable reflection upon such, the idea was widely disseminated that soldiers thus volunteering to assist in farm work were not to be regarded as "shirkers" but on the contrary as men doing a double patriotic duty, by fighting and by keeping their brother fighters alive.

In Great Britain the measures and appeals of the government have shown no less appreciation of the importance of agricultural work. Steps were early taken to organize the agricultural forces and to increase the food production. The situation called attention to certain conditions in that country which attempts were made to remedy by a readjustment of the systems of farming, and by organizing systematic means for providing labor and increasing the food returns from the land under cultivation. In directing public attention to the need of special efforts, the president of the Board of Agriculture expressed the conviction that "if agriculture had made no more progress in Germany than it has in the United Kingdom during the period 1895–1915, the German Empire would have been at the end

of its food resources long before the second year of the war;" and he explained further that the war was being fought by that country quite as much on an agricultural as on a military organization of the nation.

In an appeal to farmers for an increase in the food production of England Lord Selborne said: "You have something more on your shoulders than your own business to-day. You are no longer individual farmers making your own fortunes or losing them. You are trustees on your own land to do your best for England. You have your duty quite as clear and as definite as the captain of a cruiser or the colonel of a battalion. England has a claim on you farmers, men and women of every class, as clear as she has on our sons and husbands to go and serve in the trenches."

The force of the situation in Great Britain is illustrated by the fact that of the total area of cultivated land, two-thirds is in permanent grass and only one-third in cultivated crops, whereas in Germany the proportion is exactly reversed; and, furthermore, by the fact that even in 1915, when the wheat crop was the largest for many years, three-fourths of the wheat supply of Great Britain had to be imported. In 1915 the United Kingdom imported agricultural products valued at £276,803,000, whereas in the year before the war France spent only £60,000,000 for imported food products.

Similarly, in Germany the need for the greatest possible production of food has been impressed upon the people. The thorough cultivation has been urged of every available piece of land on farms and in towns, and societies have been formed to take the work in hand. Efforts have been made, for example, by the Moor Culture Union to increase vegetable growing on moor land, the society announcing allowances to disabled soldiers settling on such lands.

The measures adopted by the various nations are of much interest. The French Government early applied organization to the resumption of farming in affected areas and its continuance on an efficient basis elsewhere. To save the crops the small holdings were "pooled," the inhabitants of the villages who remained being grouped together for that purpose and the assistance of the military given when circumstances allowed. The government also took measures to prevent the wholesale slaughter of live stock, first suppressing the customs duty on practically all food stuffs including frozen meat, and then excluding from requisition for army purposes cows in milk or in calf, broad mares, premium sires, pedigreed stock, heifers, and plow oxen. Similar measures were taken in Great Britain and Germany. In the districts of France that had been invaded, the peasants were in need of horses, implements, seeds, fertilizers, forage, etc. To provide these the government made advances to the peasants, and to prevent the credit banks from breaking down from demands upon them it loaned

money to the Caisses Regionales de Credit Agricole, which in turn advanced money to the cooperative societies. Steps were taken to increase the amount of gardening carried on, by putting the opportunity for cultivating gardens within reach of even the humblest. The services of schoolmasters were enlisted to instruct children in gardening and to carry on model gardens.

To direct these efforts a "committee of agricultural action" was formed in each commune. These committees have formed a part of the government's plan for mobilizing agricultural labor, and have also become responsible for the cultivation of farms or holdings which have fallen out of use, the supply of seeds, fertilizers, etc.

In Germany systematic provision has been made for the cultivation of the land—selecting the crops most needed, for providing fertilizers and feeds, and economy in the utilization of agricultural products. In addition to its previous agencies and its food bureau, an imperial office for vegetables and fruit, to further the production, sale, and preservation of fruit and vegetables, was established the past year, with power to provide for the growth of the necessary amount of these supplies and their preservation.

In Great Britain the organization for agriculture has been greatly extended and strengthened. War agricultural committees and borough war food societies have been organized extensively for the assistance of farmers and to secure further allotments of land for cultivation. Attention has been turned to the utilization of land not ordinarily employed in agriculture, such as private parks, golf links, pleasure grounds, etc., as well as bringing more land into cultivated crops, employment of waste woodland for raising pigs, etc.

The farmers have been urged to plow up the poorer of the permanent pastures, shorten the period of grass and clover in rotations, bring the remaining grass into the highest stage of production to enable it to carry more stock, reduce the acreage of bare fallow, and to cultivate more extensively crops for food and for animals.

The labor problem has been a difficult one in all the countries. In Great Britain persons employed in certain agricultural occupations have been exempted from military duty, but despite this, it is estimated that up to the middle of 1916, 320,000 men had been taken from the land. Special efforts have been made to secure labor at critical times, as during harvest, by a national volunteer movement, and women have been drawn into agricultural occupations as never before. In this they have shown marked adaptability and brought much favorable commendation on their services. Nearly every issue of the Journal of the Board of Agriculture gives accounts of the successful and satisfactory employment of volunteer women laborers, frequently drawn from classes not accustomed to outdoor work. Women's committees have been active in securing recruits, and to

overcome prejudice in some sections and convince farmers of their fitness for farm work, agricultural demonstrations have been held by women in doing various kinds of operations, such as plowing, handling teams, shearing sheep, etc.

The employment of women is even more extensive in other countries at war, and in many places the temporary employment of soldiers has been of very great assistance. The Army Council in Great Britain issued instructions the past season that as far as possible farmers be loaned draft horses, mules, and drivers for help in harvesting in the neighborhood. In Germany special attention was given this year to the prompt and proper harvesting of crops. In many cases public work of all kinds was interrupted in order to set free labor for that purpose. The extensive granting of furloughs by the military authorities contributed considerable supplies of soldier labor. In some sections the help of school children was enlisted in gathering the potato crop. France, Germany, and England to some extent, have made use of prisoners of war in carrying on farm work, the custom being to require the employer to pay a small wage for the services and provide suitable conditions for living. The results have generally surpassed expectations.

The various measures in aid of agriculture have presented fine examples of cooperation between national, state, and local agencies. There has been cooperation between the civil and military branches, supported by a realization of the necessities of each, and between governmental and private organizations, often formed voluntarily for the purpose. The strength which this union of effort has given has enabled agriculture to maintain itself under most trying conditions.

But the measures for maintaining the food supply and other necessities have not stopped with the physical means of production. They have extended to advice and direction on the side of better farming, the conservation of supplies, and the utilization of new sources. The effort has tested ingenuity and resourcefulness to an unusual degree, and in this direction has led to new demands upon the various classes of agricultural institutions. It is interesting to note especially the effect upon the activities of the experiment stations and other agencies of research.

As was natural, there has been a decrease in the kind of activity which has characterized the European stations in normal times. The product of their past work has, however, become a source of great strength and resourcefulness in the countries at war. It has been drawn upon to a hitherto unprecedented degree, even that of more theoretical character. The years of experiment and investigation and application have been realized upon in a way which has furnished renewed conviction of the practical value of such effort. Coupled

with systematic agricultural education and the various forms of instruction and advice given upon farming, it has enabled effective resistance and decreased suffering.

The forces of many of the experiment stations have been considerably depleted by the war, through drafts for field service and death, and through the diversion of their activities in other directions. A station in Austria reports that it has been turned into a hospital; others have been largely diverted to making the necessities of life, serum, war munitions, etc.; a prominent investigator in Russia writes that he is now occupied in making preserved foods for the army on a commercial scale. In general the investigation is taking more practical forms, even among men whose previous work has been especially along theoretical lines.

The director of the Rothamsted Station, writing at the close of last year, said: "The war is of course affecting us, though less than we thought it would. My young men have now practically all gone or are on the point of going, but their places are being filled by women so that the work continues. Naturally, of course, the objective has altered and the more academic problems are put on one side in order that more urgent matters can be dealt with. Much of our work now is advisory and some very interesting problems are turning up."

This advisory work and the making of tests and trials of various kinds are being participated in generally by the agricultural institutions in England and other countries. Nearly every number of the Journal of the Board of Agriculture contains notes on feeding stuffs, with suggested rations, prices per food unit, and similar information, supplied by the Animal Nutrition Institute of Cambridge University; advice as to sources and values of commercial fertilizers occupies a prominent place, and there are reports of numerous simple practical trials of fertilizers and feeds for immediate application. In some countries rules for the practical farmer are being worked out, and elsewhere tests made of new materials to serve as substitutes in agriculture or to replace the necessities of life in time of scarcity and high prices.

The maintenance of the industry on an efficient basis, with many of the ordinary supplies of fertilizers, feed, spraying materials, etc., diminished or cut off, has taxed the fund of knowledge and the resources of agricultural science. The high price and scarcity of copper has led to experiments to secure substitutes for copper salts in fungicides. The hot water method is being reverted to in treating seed for smut, and lime-sulphur is being given wider use. In France, unusually heavy losses were sustained from black rot in the vineyards, because of the inability to spray as much as usual.

Everywhere special stress is laid on the control of diseases and other injuries of standard crops like cereals, potatoes, beets, and grapes, to protect the food supply. We read, also, of efforts to prevent losses other than those due to insects and plant diseases, such as the killing off of wild animals, birds, etc., which injure or feed upon farm and garden crops, and of restrictions placed on the feeding of wild game. Unusual stress is laid upon procuring good seed which will yield large returns, and special efforts have been made to provide such supplies. Plant diseases have been studied mainly from the practical side, with special reference to their control. The entomological studies have dealt largely with the relation of insects to the spread of disease.

Naturally there has been a great deal of work along food lines, with tests of various kinds of material for human food and for feeding stuffs. Yeast preparations, for example, have been devised as substitutes for meat, and found very digestible, and an egg substitute has been made from blood serum. Food preservation has taken great strides, especially desiccation by freezing or drying.

A process has been devised for preparing a cattle food from potatoes which can be kept for a long time with small loss, by fermenting small and refuse potatoes in vats by means of special cultures. To meet the need for stock feed in Germany, methods have been perfected for utilizing straw, peat, and other coarse materials by chemical means and by fermentation, reinforcing the product with dried yeast or with potato flakes and molasses. Many substitutes for oats have been devised and experimented with, among others one called chicory crumbs, made from dried chicory roots.

In veterinary lines there has been much investigation upon antiseptics to take the place of more expensive ones, sugar and salt being found effective in many cases in the treatment of animal wounds. The use of polyvalent serum, formerly used in the treatment of human wounds, has been applied to animals. Some of the institutions formerly prominent in research work have been quite extensively occupied in serum making. Considerable work in the veterinary line is reported as coming from the field service instead of the laboratory.

In Germany there has been much activity in the fixation of atmospheric nitrogen, for general uses and for fertilizers, some marked advances having been made in the direction of efficiency and economy. Small beets, cull apples, beet residues, etc., are being employed in alcohol making; and many studies are reported on vegetable sources of oil.

The testing of farm machinery has been given special impetus on account of shortage of labor, and in some sections cooperative farm implement societies were formed to provide funds for their purchase

or joint ownership. Of late, however, some difficulties have been experienced in securing the allotment of petrol for their operation. It was announced during the past summer that the Italian Government contemplated extensive purchases of labor-saving agricultural machines, to meet the difficulties caused by lack of farm hands—a new experience in that country.

Naturally the effect on the character of the agricultural literature from abroad has been quite marked. The standard journals come less frequently and several have been suspended. Many of the research articles now published relate to work done prior to the war, rather than current investigation; and summaries of old work are common, to point out the practical application of the results. The more strictly scientific publications, especially the publications of scientific academies and the general review journals, show a much reduced size as compared with the volumes of 1913 and 1914. This is, of course, to be expected, and the wonder is, not that so relatively little but that so much new investigation is being recorded at this time.

As noted above, there is unusual activity in the direction of popular articles based on good scientific practice, results of tests of substitutes for the customary articles of food, feeding stuffs, fungicides, fertilizers, textiles, etc., immunization against disease, and advocacy of the raising of small animals for food, such as poultry, rabbits, goats, etc., the latter occupying much space. There are reports of field crops tried out to supply local deficiencies, such as oilseeds and fiber plants in Germany; new varieties developed with a view to increased production on limited areas, tests of crops in regions in which they have not previously been grown to advantage, such as sugar beets in southern France, the feeding value of various unusual or waste products, and the like.

Several standard periodicals have suspended publication, among them apparently the Annales de l'Institut Agronomique de France and Annales de l'Ecole Naturale Agronomique de Montpellier; and nearly all the Belgian literature has ceased entirely. A notable exception is the Bulletin Agricole du Congo Belge, published by the Belgian Ministry of Colonies, which is now being issued in London, and two numbers of a new series Etudes de Biologie Agricole, which have been published by this ministry.

The agricultural literature from France has considerably diminished. Practically no scientific literature has been received from Germany since June, 1916, presumably on account of difficulties of transportation. The Italian literature shows less variation from the previous subject matter than does the French, German, and English.

The official organ of the stations in that country, and also that of the Hungarian stations, has shown but little change.

Very many of the agricultural colleges and schools have felt the effects of the war. For example, in England the Royal Agricultural College at Circnester, and the Agricultural and Horticultural College at Uckfield have been closed, and Armstrong College has been taken over as a military hospital, its agricultural department being temporarily housed in a dwelling.

Many of the French schools of agriculture had to close their doors on the outbreak of the war, but arrangements have since been made to open most of them. The national schools of agriculture at Rennes and Montpellier are being occupied by the sanitary service. A considerable number of the practical schools of agriculture and the farm schools have resumed operation, and several of these are receiving soldiers injured in the war.

In Austria twelve farm schools, thirty-five winter schools, and seven elementary forestry schools were temporarily closed on account of the war. Several minor institutions in Germany closed their doors temporarily, and the courses and attendance at the larger universities were much affected.

It is interesting to note that for the past two years the program of the British Association meetings has shown indications of the war's influence. The address of the president of the Agricultural Section last year dealt with the subject of farming and food supplies in time of war, showing the share contributed by British agriculture to the national food supply, and the extent to which it had assisted in making good the lack of supplies cut off by the war. This year the presidential address before that section was by Dr. E. J. Russell, director of the Rothamsted Station, and was on the subject of The Possibilities and Prospects of Increased Food Production.

The bulk of Dr. Russell's address was devoted to a consideration of the means of increasing the yield per acre, and of reducing the cost per acre and the uncertainties of production. He pointed to certain modifications and adaptations in the interest of larger production, notably a closer coordination of crop variety, soil and climatic conditions, increased efficiency in fertilizer treatment, and improvement in the management of barnyard manure to avoid waste. He also referred to the need of agricultural education to raise the ordinary farmer to the level of the good one, to the extension of the area of land under cultivation by the reclamation of waste, and to the substitution of arable crops for grass. The manner of treatment of the subject showed a broad grasp both of the opportunities and the means of extending production; and was typical of the liberal, scholarly study which is being given the subject at this time.

The war has gone a long way to impress upon governments and the public generally the vital position which production occupies and the advantages of the new agriculture. The supreme importance of scientific research in all branches has been impressed upon the countries of Europe by the most remarkable demonstrations ever furnished. In these demonstrations and convictions the indispensableness of science to an adequate agriculture has been given a new understanding; and in the general results the institutions and working forces charged with the prosecution of science and education in agriculture have richly shared.

## RECENT WORK IN AGRICULTURAL SCIENCE.

### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Chlorophyll, G. Cusmano (Ann. Chim. Appl. [Rome], 5 (1916), No. 3-4, pp. 97-117, pl. 1, fig. 1).—This is a general review of the work on chlorophyll. The subject is discussed under the following divisions: The action of alkali and acid on chlorophyll; the isolation of chlorophyll and separation into its two constituents; the carotinoids; comparison of the pigments of the leaves; and the structure of chlorophyll. A table showing the amounts of the various green and yellow coloring substances of the leaves and also one showing the decomposition products and derivatives of chlorophyll are submitted.

Bean oil (oil of Phaseolus vulgaris), F. WITKE (Chem. Ztg., 40 (1916), No. 19-20, pp. 147, 148).—The following constants for an oil extracted by benzene from the air-dried material are submitted: Yield, 2 per cent; acid value, 17.2; saponification value, 179.2; ester value, 162; iodin value, 97.9; Hehner value, 78.2; unsaponifiable matter, 5.6 per cent; phosphorus, 0.98 per cent; lecithin, 25.6 per cent; and refractive index at 25° C., 1.4865. The fatty acids were isolated in the usual manner and yielded the following constants: Saponification value, 193.1; iodin value, 124.6; acetyl value, 52.7; acetyl acid value, 175.4; acetyl saponification value, 228.1; and refractive index at 38°, 1.4691.

The disagreement in the results obtained compared with those previously reported is briefly discussed.

The fatty oil from the seed of Styrax japonica, H. Okada (Yakugakuzasshi (Jour. Pharm. Soc. Japan), No. 400 (1915), pp. 657-665).—The author obtained a yield of 45 per cent of a greenish-yellow oil with a red fluorescence from the cold-pressed seed.

The following constants were obtained for the oil: Acid value, 1.1; saponification value, 190.5; Hehner value, 94.7 per cent. The solid acids consisted of an equal mixture of stearic and palmitic acids, while the liquid acids consisted of oleic and linoleic acids. The unsaponifiable substance crystallized in glistening needles, with a melting point of 116° C.

The galactan of Larix occidentalis, A. W. Schorger and D. F. Smith (Jour. Indus. and Engin. Chem., 8 (1916), No. 6, pp. 494-499).—The authors have found that the wood of the western larch (L. occidentalis) contains approximately 10 per cent of a galactan not previously described. The galactan has been named e-galactan. On hydrolysis it yields only galactose. The determination of galactans by oxidation to mucic acid with nitric acid according to the method of Tollens is deemed unreliable. Galactans have been shown to be characteristic of several of the common conifers.

The synthesis of acetaldehyde in fruits, H. MÜLLER-THURGAU and A. OSTERWALDER (Landw. Jahrb. Schweiz, 29 (1915), No. 5, pp. 508, 509).—In a study on the influence of sulphur dioxid on yeasts and bacteria in wine and fruit juices it was observed that the sulphurous acid was in some way so chemically bound as to become inactive. Further investigation showed that the sulphur dioxid was bound by the aldehydes present in the juice. Aldehyde

was found, however, only in fully ripe fruits. In pears the amount was found to increase gradually until a maximum was reached in the overripe stage of the fruit. The presence of aldehyde was only occasionally demonstrated in apples, and in one sample of grapes examined was absent.

The urease content of certain beans, with special reference to the jack bean, J. G. Mateer and E. K. Marshall, Jr. (Jour. Biol. Chem., 25 (1916), No. 2, pp. 297-305).—The authors have demonstrated that the jack bean (Canavalia ensiformis) contains about 15 times as much urease as the soy bean. The extract from the jack bean, however, contains much less solid residue than the soy-bean extract. The urease appears to be specific for urea, just as is the enzym obtained from the soy bean. The use of the jack-bean urease for the rapid removal of urea from solutions in which as little contaminating material as possible should be added, and its use for quantative urea determinations is indicated. The presence of urease was also established in the urd bean (Phascolus aureus) and the horse gram (Dolichus biflorus).

Notes on collodion membranes for ultrafiltration and pressure dialysis, G. S. Walpole (Biochem. Jour., 9 (1915), No. 2, pp. 284-297, figs. 5).—This article describes the preparation of collodion test-tube shaped bags and their use for simple ultrafiltration and dialysis experiments. On account of their lack of uniformity and the difficulty of accurate reproduction their use is not recommended for careful work.

Flat membranes are prepared by pouring alcohol-ether solutions of collodion on leveled plate glass and then plunging the film, after partial evaporation of the alcohol and ether, into water. With proper precautions films of remarkable uniformity can be prepared. It is suggested that "in these films, more than in other ultrafilters in general use, the channels leading through the gel structure from one side to the other are of a certain uniformity in size. None of them is large enough to allow any antigen to pass; but the structure is highly porous and, because there are many such channels, rapid ultrafiltration results."

The arrangements of apparatus in which the flat membranes and also the test-tube shaped membranes can be utilized for ultrafiltration and pressure dialysis are described in detail.

A rapid filter for turbid liquids, R. C. Shuey (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 6, p. 523, fig. 1).—An ordinary suction filter, using the paper pulp used by distillers, and its manipulation are described.

A rapid method for comparing the decolorizing efficiency of charcoals, L. Wickender and J. W. Hassler (Jour. Indus. and Engin. Chem., 8 (1916), No. 6, pp. 518, 519, fig. 1).—A method which is rapid and enables charcoals to be classified with great ease and accuracy according to their decolorizing efficiency is described. A solution of Soudan III or Oil Red RN in kerosene is used for the test. The solutions filter rapidly and come through clear and bright. The preparation of a standard scale for classifying the charcoals and also a simple colorimeter which facilitates the procedure are described.

A new colorimeter, C. F. Sammet (Jour. Indus. and Engin. Chem., 8 (1916), No. 6, pp. 519-521, fig. 1).—The author describes a colorimeter which is easily adjusted. Although designed for reading the color of turpentine, it is equally well adapted for other colorimetric work when standard glasses can be employed and the solution does not attack the metallic cell.

A Kjeldahl fume remover, F. G. MEBKLE (Jour. Indus. and Engin. Chem., 8 (1916), No. 6, pp. 521, 522, figs. 3).—An apparatus consisting of a lead pipe of 0.5 in. inside diameter, to which are soldered as many 3-in. lead tubes (\frac{1}{2} in. diameter) as desired, is described. The small tubes are fitted with rubber stoppers, which are in turn fitted to the flasks used in the digestion. The acid

fumes are disposed of by passing into a sink pipe which is washed with a stream of water or in some other convenient manner.

A small apparatus for two flasks is also described.

Contribution to the determination of citric-acid-soluble phosphoric acid by the iron-citrate method, N. Zachariades and J. Czak (Ztschr. Landw. Versuchsw. Österr., 18 (1915), No. 7, pp. 472–475).—Experimental data of the analysis of a number of slags by the iron-citrate method are submitted. From these data the authors conclude that the addition of hydrogen peroxid for the purpose of oxidizing any hydrogen-sulphid combinations is usually superfluous, especially if the odor of hydrogen sulphid is only weakly perceptible. The precipitate need not be filtered immediately, as has been previously recommended. The data submitted check very well with results obtained by the procedure of Popp.

Note on the determination of phosphorus in plant materials, A. W. Christie (Jour. Indus. and Engin. Chem., 8 (1916), No. 6, p. 511).—Experimental data submitted from the California Experiment Station indicate that the ignition of the sample with magnesium oxid is a quick and accurate method of oxidizing the organic material in the determination of total phosphorus. Oxidation with fuming nitric acid was found to be unsatisfactory.

Studies on the determination of sulphur as barium sulphate, P. L. Blumenthal and S. C. Guernsey (Iowa Sta. Research Bul. 26 (1915), pp. 390-436).—The purpose of the investigation reported was chiefly "to discover the magnitude and causes of the error involved in the usual method of determining total sulphur, particularly in lime-sulphur solutions; . . . to ascertain the method best adapted to estimating total sulphur . . . and to extend our knowledge of the mechanism of the reaction." The history and use of the method are reviewed and discussed in some detail.

Experimental results with potassium and sodium sulphates, showing the effect of various rates of addition of barium chlorid in definite quantity and of varying strengths at constant volume and acidity, demonstrate that there is little choice between the use of 5 and 10 per cent barium chlorid, the time of addition being slightly more important. Five per cent barium chlorid added at the rate of 5 cc. per minute was found to yield the best average results in the work at hand. Various strengths of acid were found not to influence the results to any great extent, although a low acidity was preferable (2 per cent or less).

In studying the effect of various salts on the precipitation it was found that when sodium salts were the only impurity very concordant analyses could be obtained. In the presence of calcium the results obtained did "not differ markedly from the figures obtained in the presence of other salts. The same variations occur, and again the necessity of working under exactly uniform conditions is emphasized." The presence of magnesium in general yielded high values. From a general consideration of the analytical results the authors arrive at the conclusion that "a pure precipitate of barium sulphate is not to be obtained by any ordinary precipitation method. The best values are due to a balancing of errors, and to insure uniformity of analyses the strictest attention must be given to maintaining definite and identical conditions in the system."

For accurate lime-sulphur analyses the following procedure is recommended: One aliquot is oxidized with sodium peroxid, heated, diluted, acidified, boiled, precipitated rapidly with 5 per cent barium chlorid, and filtered through a Gooch crucible after an hour's standing. A general idea of the amount of sulphur in the definite volume of solution is thus obtained. The volume of the final determination is so adjusted that each cubic centimeter will contain

about 1 mg. of barium sulphate. The final volume of the solution after precipitating the sulphate should thus be about 250 to 350 cc. After oxidizing a suitable aliquot with sodium peroxid, heating to hasten the oxidation, and acidifying, the solution should be boiled to drive out dissolved gases, exactly neutralized, and an amount of concentrated hydrochloric acid added so that the volume percentage of hydrochloric acid does not exceed 2 per cent. After diluting the acidified solution to the proper volume it is heated to boiling and precipitated hot with 20 cc. of 5 per cent barium chlorid added from a burette at the rate of from 5 to 10 cc. per minute, preferably at the slower rate. solution should not be shaken or stirred. The beaker and contents after the precipitant has been added are set aside and allowed to stand for at least 12 hours before filtering. After filtration the precipitate is washed with cold water until free from chlorids, using a uniform quantity of wash water, 150 cc. added in 15 cc. portions usually sufficing to free a precipitate of this size from chlorids, and introducing a negligible loss due to solubility of barium sulphate.

In an attempt to increase the knowledge of the mechanism of the reaction other precipitants for sulphur were tried. The authors conclude that they have no better explanation for the mechanism of the reaction than those offered by earlier investigators. The necessity for following a definite set of conditions in sulphur analysis is strongly emphasized.

A list of 43 references cited is appended.

The quantitative determination of the total protein and nonprotein substances of muscle. Improved technique, N. W. Janney (Jour. Biol. Chem., 25 (1916), No. 2, pp. 177-183).—The following modified quantitative procedure is outlined:

"The fresh muscle is freed from all adherent fat and connective tissue, passed through a meat grinder, and thoroughly mixed. About 10 gm. is weighed by difference into a beaker from a weighing glass provided with a ground glass lid. Fifty cc. of 95 per cent alcohol is added and the contents of the beaker heated, with stirring, until the alcohol boils. The liquid is then decanted through an ordinary round filter of 12.5 cm. diameter, which has previously been extracted with alcohol and ether, dried, and weighed. This treatment of the protein with alcohol is once repeated.

"The coagulated muscle is next extracted in a similar manner with 400 cc. of boiling water in four portions, and then brought quantitatively on the filter. The filter is now carefully folded about the protein material, which is gently inserted into an extraction hull and extracted three hours in an ordinary Soxhlet apparatus with 95 per cent alcohol. The 95 per cent alcohol is then replaced by absolute alcohol and the extraction continued for a period of 15 hours. Care must be taken that the filter projects beyond the upper level attainable by the solvent, which must completely surround the protein. After completion of the extraction the filter with the pure protein is removed from the apparatus, dried to constant weight at 105° [C.] in a weighing glass provided with a ground glass lid, and the previously ascertained weight of the filter paper deducted."

When required, the nonprotein substances are determined by deducting the percentage of protein found from the percentage of total solids.

The protein content of muscle, N. W. Janney (*Jour. Biol. Chem.*, 25 (1916), No. 2, pp. 185-188).—This material has been essentially noted from another source (E. S. R., 35, p. 315).

The ninhydrin reaction with amino acids and ammonium salts, V. J. HARDING and F. H. S. WARNEFORD (Jour. Biol. Chem., 25 (1916), No. 2, pp. 319-

335).—The experimental data demonstrate that ammonium salts of weak acids react positively with ninhydrin in concentrations of 1 per cent. In very high concentrations the ammonium salts of strong mineral acids give a positive ninhydrin reaction. Reducing agents increase the sensitiveness of the ninhydrin reaction with ammonium salts.

"In the presence of pyridin and in a concentration of 1 cc. = 0.05 mg. of nitrogen, all ammonium salts react positively with triketohydrindene hydrate. The amount of decomposition of the ammonium nitrogen was found to be independent of the acid radical attached and possessed a constant value of 0.018 mg. nitrogen; the blue coloration is due to the ammonium salt of diketohydrindylidene-diketohydrindamin."

A theory as to the mechanism of the reaction with amino acids and ammonium salts is suggested.

The ninhydrin reaction with amins and amids, V. J. Harding and R. M. MacLean (Jour. Biol. Chem., 25 (1916), No. 2, pp. 337-350).—"The ninhydrin reaction is given by organic bases of the type RCH₂NH₂, and R₂CHNH₂ where one radical is negative in character. Other bases which readily yield ammonia or are readily oxidized give the ninhydrin reaction. With the fatty amins and in the presence of pyridin the strongest reaction is given by the simplest members. Amids give no reaction with ninhydrin. Guanidin and its derivatives give a negative test."

The nonspecificity of the ninhydrin reaction for amino acids, especially in very small amounts and in the presence of large amounts of ammonium salts, is emphasized.

On the determination of phytosterol in animal fats according to Bömer's acetate procedure with the separation of the stearins by precipitation with digitonin, B. KÜHN, F. BENGEN, and J. WEWERINKE (Ztschr. Untersuch. Nahr. u. Gcnussmtl., 29 (1915), No. 8, pp. 321-329).—The authors outline a modified procedure as follows:

Fifty gm, of fat is heated with 100 cc. of alcoholic potassium hydroxid (200 gm. KOH dissolved in 70 per cent alcohol and made up to 1 liter) for 15 minutes on a water bath. The clear soap solution is diluted with 150 cc. hot water and then 50 cc. hydrochloric acid (specific gravity 1.124) is added. The clear fatty acids are then separated from the KCl-glycerin mixture by filtration. To the warm liquid acids 25 cc. of a 1 per cent solution of digitonin in 96 per cent alcohol is added, and the mixture is thoroughly stirred and allowed to set on the water bath at a temperature of 70° C. for from 0.5 to 1 hour, according to the amount of stearins present. To the mixture, from 15 to 30 cc. of chloroform is now added and the precipitate carefully filtered on a Witte plate with gentle suction. The precipitate is washed from three to five times with chloroform and in the same manner with ether. When free from fatty acids it is dried for ten minutes at from 90 to 100°. The precipitate is now strongly boiled with from 3 to 5 cc. of acetic anhydrid for about five minutes, in which time the reaction is usually complete. Four volumes of 50 per cent alcohol are now added and the mixture cooled. After from five to ten minutes the precipitated acetate is filtered through a small filter, washed with 50 per cent alcohol, and then recrystallized from ether solution.

Analytical data of the melting points of stearin acetates obtained from 75 different samples of fats and mixtures are submitted.

The determination of stearins by means of digitonin, O. Pfeffer (Ztschr. Untersuch. Nahr. u. Genussmtl., 31 (1916), No. 2, pp. 38-40).—The procedure modified by Kühn et al. (see previous abstract) was found to yield excellent results.

The physiology of souring of pure and watered milk, F. Reiss (Ztschr. Untersuch. Nahr. u. Genussmtl., 31 (1916), No. 2, pp. 41-45).—From experimental data submitted it is concluded that within rather wide limits of milk watering in the course of lactic acid fermentation amounts of lactose are fermented which are inversely proportional to the degree of watering. While more conclusive evidence is necessary to answer the question whether the degree of acidity can be definitely used as an index of the amount of water, it is deemed certain that from the degree of acidity of sour milk it can safely be determined whether or not the milk was originally watered.

The gravimetric determination of reducing sugars in cane products, G. P. Meade and J. B. Harris (*Jour. Indus. and Engin. Chem.*, 8 (1916), No. 6, pp. 504-509).—In clarifying the sugar solutions the authors found that different results were obtained by the use of varying amounts of neutral lead acetate solution.

"Carbonate, sulphates, and oxalates are not interchangeable as deleading agents, oxalates giving results from 4 to 5 per cent higher on the weight of copper than where either of the others is used. Kieselguhr only, without the use of lead or other reagent, gives a clear filtrate, both with final molasses and raw sugar, and the solution offers no mechanical difficulty in the precipitation and collection of the copper precipitate. Without lead the results are slightly lower than where lead and oxalate are used."

Results obtained by weighing the cuprous oxid were about 5 per cent higher on the weight of copper than those obtained by igniting and weighing as cupric oxid. Volumetric iodid determinations of the copper checked the cupric oxid results.

It is indicated that, "under strict specifications as to the quantity and class of reagents, any method for the preparation of the solution for analysis will give results which check within themselves."

The determination of the gelatinizing temperature of the starches from the grain sorghums by means of a thermo-slide, C. K. Francis and O. C. Smith (Jour. Indus. and Engin. Chem., 8 (1916), No. 6, pp. 509-511, figs. 2).—This material has been previously noted from another source (E. S. R., 35, p. 108).

A colorimetric method for the estimation of free formaldehyde and hexamethylenamin, R. J. Collins and P. J. Hanzlik (Jour. Biol. Chem., 25 (1916), No. 2, pp. 231-237).—A colorimetric method in which the phloroglucinol reagent (0.1 gm. phloroglucinol in 10 cc. 10 per cent sodium hydroxid) is used is described.

Permanent color standards are prepared from mixtures of Congo red and methyl orange. Standard mixtures for concentrations of formaldehyde between 1:1,000,000 and 1:20,000 have been determined and are submitted. It is indicated that the procedure described is more accurate than the Romijn, the United States Pharmacopæia method, and the hydroxid pressure method. It is directly applicable for the determination of free formaldehyde in urine.

[Report of the fermentation and bacteriological section], H. MÜLLER-THURGAU and A. OSTERWALDER (Landw. Jahrb. Schweiz, 29 (1915), No. 5, pp. 537-568).—Experiments on the value of washing the fruit preliminary to pressing demonstrated that the washing did not yield a purer fermentation or a more stable product. In the reduction of the acidity of wines, partial neutralization with calcium carbonate and further reduction to any degree of acidity desired by the action of Bacillus gracilis at various temperatures was found to yield satisfactory results.

From results obtained in connection with studies on the influence of sulphurous acid on fermentation processes in wines and fruit juices, it is indicated that the amount of sulphur dioxid which actually inhibits alcoholic and the various acid fermentations so varies that no exact amount to be used can be prescribed. An investigation on the effect of sulphur dioxid on wine diseases indicated that the use of sulphur dioxid is a valuable aid in preventing the lactic-acid disease which is so prevalent in certain fruit juices, especially those obtained from overripe pears and apples. On account of the presence of aldehydes in the juices the sulphurous acid soon becomes inactive, so that for reliable results sufficient quantities of potassium metabisulphite should also be added, but because of the continued production of aldehyde during fermentation the quantity of sulphur dioxid and potassium metabisulphite necessary should be largely regulated by the activity of the fermentation. An undue excess is to be avoided at the beginning of the fermentation, as it may injure the bacteria (B. mannitopoeum and B. gracilis), although not the yeasts.

[Report of the chemical section], W. J. BARAGIOLA, C. GODET, and O. SCHUPPLA (Landw. Jahrb. Schweiz, 29 (1915), No. 5, pp. 568-572).—These pages briefly report the results obtained in the investigations on the difference between acid content and degree of acidity; analytical investigations on the ripening of grapes and the wine obtained therefrom; acid reduction in wine in relation to its analysis, physicochemical properties, and hygienic value; the fermentation of grape must under paraffin oil; and the various combinations of sulphur in wine and their determination.

#### METEOROLOGY.

Weather as a business risk in farming, W. G. Reed and H. R. Tolley (Geogr. Rev., 2 (1916), No. 1, pp. 48-53, figs. 4; abs. in U. S. Mo. Weather Rev., 44 (1916), No. 6, pp. 354. 355, figs. 3).—It is pointed out in this article that the occasional occurrence of unfavorable weather conditions is a risk which must be recognized by successful farmers, and it is stated that in the case of phenomena whose distribution follows the "normal law of frequency" this risk may be determined with a fair degree of accuracy. A method of determining the risk of frost occurrence is described in this paper, and the opinion is expressed that a method of computing the risk from other more complicated phenomena can be worked out.

"To compute the time available for plant growth in a given proportion of the years the most satisfactory method is that based on the risk at each end of the growing season. If the chance of safety on a given date in spring is one-half and that on a given date in fall is one-half, the chance of safety for the whole period between is one-half multiplied by one-half; that is, one-fourth. For many important crops about a four-fifths chance of safety is essential for continued success. . . . For any place the length of the available growing season (that is, number of days for which the chance is four in five), beginning at the date when the frost risk falls to 10 per cent, is the number of days between this date and the date on which the chance of fall frost rises to 10 per cent."

A table is given which simplifies the computation. It is stated that "although this method of determining business risk is subject to limitations because of the shortness of the individual records, a careful examination of the records shows that in the large the computed dates on which the frost risk rises (or falls) to 10 per cent, when compared with the actual number of occurrences, is a very close agreement. From a total of 27,157 observations the lack of agreement between the computed and counted cases was but 17 in 10,000."

Critical period of growth (U. S. Dept. Agr., Nat. Weather and Crop Bul. 22 (1916), pp. 2, 3, fig. 1).—Attention is called especially to the use of rainfall charts in relation to the critical periods of corn, the most important of which is the ten days following the date of blossoming.

Weather and the yield of corn (U. S. Dept. Agr., Nat. Weather and Crop Bul. 14 (1916), p. 2, fig. 1).—The relation between the yield of corn and the rainfall in Ohio, Indiana, Illinois, Iowa, Nebraska, Kansas, Missouri, and Kentucky for the 28 years from 1888 to 1915, inclusive, is shown in a diagram and briefly discussed. The most striking fact brought out is that whenever the rain for July has been above the normal the yield was above the normal in every instance. Whenever the rainfall was below the normal the yield has also been below in every year except five.

The four greatest corn States (*U. S. Dept. Agr.*, *Nat. Weather and Crop Bul. 15* (1916), p. 2, fig. 1).—It is shown that the average yield of corn for Indiana, Illinois, Iowa, and Missouri is 32 bu. per acre, and that the average July rainfall for the region covered by these States is 3.9 in. The preeminence of these States in corn production is shown to be closely correlated with the July rainfall.

Rainfall and temperature and corn yield (*U. S. Dept. Agr.*, *Nat. Weather and Crop Bul. 18* (1916), pp. 2, 3, fig. 1).—The effect of July rainfall and temperature on the yield of corn in Ohio during the period from 1854 to 1915, inclusive, is shown in a diagram and briefly discussed. The July rainfall is shown to be the dominating factor.

Weather and yield of potatoes (U. S. Dept. Agr., Nat. Weather and Crop Bul. 19 (1916), pp. 2, 3. fig. 1).—A study of the effect of temperature and rainfall upon the yield of potatoes in Ohio, Michigan, and New Jersey is reported, showing that the temperature of July is the most important weather factor in those States. A cool July is most favorable.

Monthly Weather Review (U. S. Mo. Weather Rev., 44 (1916), Nos. 5, pp. 243-319, pls. 9, figs. 18; 6, pp. 321-379, pls. 14, figs. 28).—In addition to weather forecasts, river and flood observations, and seismological reports for May and June, 1916; lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology; notes on the weather of the months; solar and sky radiation measurements at Washington, D. C., during May and June, 1916; condensed climatological summaries; and the usual climatological tables and charts, these numbers contain the following articles:

No. 5.—Circumhorizontal Arc Observed, by J. T. Gray; The Blue of the Sky and Avogadro's Constant, by D. Pacini; Photography of the Zodiacal Light and Counterglow, by A. E. Douglass; Propagation of Sound in the Atmosphere, by E. van Everdingen; Spontaneous Ionization of the Aqueous Vapor of the Atmosphere, II, by G. Oddo; Variation of the Emanation Content of Springs, by R. R. Ramsey; Planetary Phenomena and Solar Activity, by T. Köhl; Free-air Data by Means of Sounding Balloons, Fort Omaha, Nebr., July, 1914 (illus.), by W. R. Blair; Meteorological Symbols (illus.), by C. F. Talman; The Coefficient of Correlation as a Measure of Relationship, by C. N. Moore; Rainfall in China, 1900-1911 (illus.), by Co-Ching Chu; American Definition of "Sleet," by C. Abbe, jr.; Two Abnormal Pressure Distributions in Italy (illus.), by F. Eredia; Fog as a Source of Water Supply, by W. G. Reed (see p. 619); A Simple Wind-Velocity Indicator for Use with the Robinson Anemometer (illus.), by B. C. Kadel; Diurnal Variation of Underground Temperature, by S. Sato; Aleksandr Ivanovich Voerkov, 1842-1916; The Chinese Weather Bureau, by Co-Ching Chu; Flood in the Lower Mississippi, Spring, 1916, by W. E. Barron; and Rainfall and Floods in China, by S. T. Suen.

No. 6.—Meteor of June 28, 1916, Over Northeastern Texas (illus.), by H. H. Martin; Observations of Meteor Trains; Meteor of May 7, 1916, in Eastern Mississippi, by J. H. Jaqua; Meteor of May 7, 1916, at Demopolis, Ala., by J. G. Whitfield; Work of the American Meteor Society, 1914 and 1915, by C. P. Olivier; Canadian Aerological Research; Use of a Flagpole in Calibrating Kite

Anemometers (illus.), by B. J. Sherry; Solar Variability, by C. G. Abbot et. al.; Tropical Rains: Their Duration, Frequency, and Intensity (illus.), by O. L. Fassig (see below); Mechanism of Cyclones, by F. J. W. Whipple; Causes Contributory to the Annual Variation of Latitude, by H. Jeffreys; Meteorological Aspects of Oceanography (illus.), by H. Pettersson; Precipitation Over the Southeast Rocky Mountain Slope (illus.), by C. Hallenbeck; Fog in Relation to Wind Direction on Mount Tamalpais, Cal., by H. H. Wright; On the So-called Change in European Climate During Historic Times, by H. H. Hildebrandsson (see below); Violent Easterly Winds at Tatoosh Islands, Wash. (illus.), by R. C. Mize; Weather as a Business Risk in Farming (illus.), by W. G. Reed and H. R. Tolley (see p. 616); and Snow Surveys in Big Cottonwood Canyon, Utah, 1912–1916 (illus.), by H. K. Burton.

On the so-called change in European climate during historic times, H. H. HILDEBRANDSSON (Nova Acta Reg. Soc. Sci. Upsal., 4. ser., 4 (1915), No. 5, pp. 31, pls. 3; U. S. Mo. Weather Rev. 44 (1916), No. 6, pp. 344–352).—From an exhaustive review of data from various sources on the subject, the general conclusion is reached "that there exist everywhere climatic variations of long and short duration, but it is not possible to prove that the climate of Europe has changed for either better or worse during historic times."

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 3 (1916), Nos. 5, pp. 224, pls. 2, figs. 4; 6, pp. 224, pls. 2, figs. 4).—These numbers contain brief summaries and detailed tabular statements of climatological data for each State for May and June, 1916, respectively.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and J. S. Sims (Massachusetts Sta. Met. Buls. 331-332 (1916), pp. 4 each).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during July and August, 1916, are presented. The data are briefly discussed in general notes on the weather of each month.

Tropical rains: Their duration, frequency, and intensity, O. L. FASSIG (U. S. Mo. Weather Rev., 44 (1916), No. 6, pp. 329-337, figs. 15).—The rainfall phenomena of Porto Rico and of Maryland are compared. It is shown that there is a fairly even distribution of rainy days throughout the year in both regions. Rains, especially excessive rains, are more frequent and more uniformly distributed throughout the year in the tropical region.

"Frequent moderate rains are generally more favorable for plant growth than heavier rains, assuming equal total amounts for the year. There is a wide range in the frequency of rains of 0.01 to 0.1 in. in Porto Rico, a condition which is probably common to all regions with pronounced differences in topography. As the amounts grow larger the range rapidly decreases. The best and most extensive tobacco plantations of Porto Rico are situated in the portion of the island having the greatest number of light rains, with a total annual amount close to the average for the entire island. The station at Caguas, typical of this region, shows a record of 160 days with rainfall from 0.01 to 0.1 in., with a total annual frequency of 262 days and a total rainfall of 68 in. In the mountains of the western portion of the island, a region noted for the abundance and fine quality of its coffee, the rainfall is very heavy. A peculiarity of the rains of this region is that they show a maximum frequency of amounts between 0.2 and 0.3 in., whereas the usual record shows a very decided preponderance of amounts less than 0.1 in."

Fog as a source of water supply, W. G. REED (U. S. Mo. Weather Rev., 44 (1916), No. 5, p. 288).—Referring to an article by Descombes, previously noted (E. S. R., 34, p. 614), it is stated that "there is apparently a close relation

between the occurrence of summer fog and the distribution of the redwood (Sequoia sempervirens) in California. In addition, a result of the fog is easily seen wherever there are single trees, such as is the case on the Berkeley Hills of the coast ranges, which are in process of reforestation. During the summer fogs the small trees are dripping with moisture, although the ground away from the trees is perfectly dry. As a result the grass beneath each tree remains green throughout the year."

The climate of Roumania in relation to dry farming, L. Georgesco (Vie Agr. et Rurale, 6 (1916), No. 11, pp. 191-194, figs. 2; abs. in Rev. Sci. [Paris], 54 (1916), II, No. 13, pp. 405, 406).—It is explained that the climate of Roumania is typically continental and on the plains is such as to make the use of dry-farming methods desirable. The annual rainfall is seldom less than 500 or more than 800 mm., the mean being about 600 mm. (about 23.6 in.) It is smaller on the plains (300 to 500 mm.), and increases with the elevation (1,300 to 1,600 mm. in the mountains). It also varies in distribution seasonally.

Even in seasons of low rainfall the amount is sufficient for good wheat crops, provided it is suitably distributed. The average annual temperature is about 10° C. (50° F.) on the plains and from 8 to 9° at the higher elevations. There are, however, wide seasonal extremes in temperature (-35 to 40°). The daily extremes are also wide. Cold, high winds are common in winter, and dry, hot winds in summer. Bright sunshine varies from 50 to 80 per cent of the total possible. The humidity of the air varies from 50 to 60 per cent in summer and from 85 to 90 per cent in other parts of the year. The climatic conditions are such as to make early seeding in the fall and late seeding in the spring necessary.

The influence of weather conditions upon the amounts of nitrogen acids in the rainfall and atmosphere in Australia, O. Masson, V. G. Anderson, D. Avery, and H. A. Hunt (*Rpt. Brit. Assoc. Adv. Sci., 1915, pp. 87-94, figs. 3*).—This is a preliminary report upon the organization of investigations covering the whole of Australia (16 stations), similar to those reported by Anderson for the region of Melbourne (E. S. R., 33, p. 617). The plan and purpose of this work and the apparatus and methods to be used are briefly described.

Discussion on smoke abatement and air pollution (*Rpt. Brit. Assoc. Adv. Sci.*, 1915, pp. 387-393).—Brief notes are given on discussions at the Manchester meeting of the British Association for the Advancement of Science, 1915, on the work of the Manchester Air Pollution Advisory Board, the work of the Sheffield Health Committee, damage to vegetation caused by atmospheric pollution by smoke, improvements in domestic fire grates, recent improvements in gas fires, and other aspects of the smoke question.

### SOILS-FERTILIZERS.

Soil temperature, G. J. BOUYOUCOS (Michigan Sta. Tech. Bul. 26 (1916), pp. 133).—A continuation for three years of the field experiments previously noted (E. S. R., 29, p. 618) is reported, together with the final conclusions drawn from the entire investigation.

"The field studies on the temperature of different types of soil, namely, gravel, sand, humus loam, clay, and peat at 6-, 12-, and 18-in. depths, showed that when the surface of all these soils was covered with a thin layer of sand they had almost exactly the same average temperature throughout the year except during a short period in the spring when thawing was taking place. . . . During the summer months the peat [had] a monthly average temperature of a few tenths of a degree higher than the mineral soils. In the fall, the sand and gravel possessed a slightly higher monthly average temperature than

the peat. Whenever rapid and sudden changes of air temperature occurred the sand and gravel warmed and cooled the fastest, followed by clay, loam, and peat, respectively. The equilibrium [was] quickly reestablished. The degree of amplitude was greatest in sand and gravel, somewhat smaller in loam and clay, and least in peat. The highest fluctuation occurred in summer and the lowest in winter. The maximum temperature was approximately the same for all types of soil, after complete thawing had taken place, but the minimum varied somewhat; it was lowest in sand and gravel, slightly higher in clay and loam, and highest in peat. . . .

"When the same types of soil were not covered with a thin layer of sand but their natural surface was allowed to be exposed to the atmosphere . . . their average temperature . . . was about the same during the fall and winter months, but varied somewhat during the spring and summer months. During the latter seasons the sand and gravel [had] the highest average temperature, the clay and loam slightly lower, and peat the lowest. . . In the spring the peat [did] not thaw and its temperature [did] not approach that of the mineral soils after complete thawing as rapidly as when its surface was covered with the thin layer of sand. Besides the average temperature the order of the maximum and minimum temperature [was reversed] in the various types of soil under the two surface conditions. . . .

"The average air temperature was lower than that of any soil at the 2-, 4-, 6-, 12-, and 18-in. depths, throughout the year. . . . The maximum temperature of all the soils at \(\frac{1}{4}\)-in. depth was about 30° F. higher during hot and clear days than that of the air at an elevation of 4 ft. The minimum temperature of all the soils except peat. however, immediately at the surface was only about 1 or 2° higher, as a monthly average, than that of the air at a height of 4 ft. . . . Unless the various soils were frozen they always had a gradient of temperature at their adjacent depths [which], however, reversed itself between day and night during the warm part of the year to the depth that the diurnal-nocturnal amplitude of oscillation of temperature extended. . . .

"The rate at which the maximum and minimum temperature waves traveled through any particular soil tended to follow approximately a mathematical law.

Thus, the lag of the maximum and minimum epochs tended to be approximately proportional to the depth in all the different types of soil.

"The decrease of the diurnal-nocturnal amplitude of temperature with the increase in depth also followed a mathematical law in all the diverse types of soil and the geometric progression law. . . . The diurnal-nocturnal amplitude of oscillation of temperature decreased in geometric progression as the depth increased in arithmetric progression, in all the different types of soil.

"The four years' data obtained on the temperature of sand to which was added different percentages of organic matter (peat) showed that during the fall and winter months all these soils had approximately the same degree of average temperature, but in the spring and summer months it varied somewhat. During the latter months the sand which received no organic matter and had a white colored surface and the peat had about the same and lower average temperature than the other soils which were treated with various percentages of peat. . . . The amplitude of temperature at the 3- and 5-in. depths was high, but approximately of equal degree in all the treated and untreated soils, but comparatively low in the peat. . . .

"The uncultivated soil had practically the same or only a few tenths of a degree higher temperature during the spring months than the cultivated and only about 1° higher during the summer months. During the fall and winter months there was hardly any difference. There did exist, however, a very marked difference in average temperature between the two bare soils and one

covered with growing vegetation. . . . Immediately upon the commencement of growth of the vegetation the temperature of the sod or grass land became decidedly lower than that of the cultivated and uncultivated soil. The maximum difference [was] reached in June and July, when the sod soil at the 7-in. depth, for instance, [was] about 6° colder than the bare soils. This difference, however, [became] smaller and smaller, so that by September it entirely disappeared, and by October the order [was] reversed; the bare plats [became] colder and the sod warmer. The latter continued to have a higher temperature throughout the fall and winter months. . . .

"In exceptionally cold weather the soil covered with vegetation and a layer of snow had 25° higher temperature than a bare soil at 3-in. depth. Certain topographic positions have a marked controlling influence upon the soil temperature. A southern exposure had about 2° higher average temperature than a northern during the spring and summer months, but during the fall and winter months both locations were equally warm. The soil temperature at a river bank was far below that of the south and north slope during the spring and summer months, but slightly higher during the fall and winter months. The marked influence of the slant of the surface with respect to the position of the sun on the soil temperature is manifested on a cultivated soil with very lumpy and uneven surface. The sides of the lumps or dead furrows facing the sun in the morning had a higher temperature than those shaded."

Fundamental interrelationships between certain soluble salts and soil colloids, L. T. Sharp (Univ. Cal. Pubs. Agr. Sci., 1 (1916), No. 10, pp. 291–339, figs. 3).—It was found in cylinder experiments that clay loam soil, exposed to natural conditions and to which surface applications of solutions of sodium chlorid, sulphate, and carbonate had been made, became very impervious to water, difficult to cultivate, and manifested the characteristics of a high degree of diffusion. Laboratory studies showed that the salts had moved downward into the lower layers of soil and that only the surface soil was affected.

"The deflocculated condition resulting from adding certain salts to and subsequently washing them from soils can be reproduced in the laboratory. The deflocculation of soils [so] treated . . . is intimately associated with the leaching of the NaCl and Na₂SO₄ down into the lower layers of soil by water. In the case of Na₂CO₂ the leaching process is not so essential for the diffusion of the soil colloids. The addition of NaCl, Na₂SO₄, and Na₂CO₃ to the soil when followed with applications of water was particularly effective in diminishing the rate of percolation through the soil so treated. NaCl and Na₂SO₄ in constant contact with the soil increased the rate of percolation, except when a comparatively dilute solution of NaCl was slowly passed through the soil for a considerable period of time.

"The soil treated with NaCl, NaOH, Na₂CO₃ and other salts, followed by leaching with water, yields a suspension in water containing approximately ten times as much solid matter as the same soil washed with water only. A real diffusion in such salt-treated soils seems evident. The soil once diffused by washing out added NaCl requires considerably more salt to completely flocculate it, than does the water-washed soil. Likewise the injured physical condition of such soils is not readily repaired by a second addition of NaCl.

"The portion of the organic matter of the soil known as humus has little or no connection with the appearance of diffusion in salt-treated, water-washed soils. The diffusion in soils treated as described above seems to be closely associated with the direct addition of sodium to or with the absorption of sodium by the soil, thereby producing a new silicate complex of a colloidal character in the soil . . . [which] is formed simultaneously with the interchange of ions occurring between the salt and the soil. The washing process serves, in the case

of neutral salts, to remove flocculating agents. The loss of calcium and magnesium from the soil bears little or no relation to the flocculation appearing in salt-treated, water-washed soils except in so far as it may be a measure of the absorbed sodium. The presence of the OH-ion does not seem to be an essential factor in the diffusion of salt-treated, water-washed soils. Na₂CO₃ and NaOH produce markedly different effects on suspensions of the soil. The acid ion of the salt is not an important factor in the deflocculation phenomena following the washing out of salts from soils. Sodium, potassium, and ammonium seem to produce the colloidal silicate complex when salts of these metals are applied to soils, while calcium does not. Dilute solutions of acids and salts possess flocculating powers on suspensions of the soil. It is not essential in every case to wash all of the salt out in order to bring about diffusion."

How much plant food is removed from soils by crops and drainage water? H. von Feilitzen (Svenska Mosskulturför. Tiäskr., 29 (1915), No. 3, pp. 193-210, fig. 1).—Lysimeter experiments on swamp soil and so-called whitemoss soil are reported, which showed that the losses of nutritive constituents in drainage water were much smaller in pastures than in cereal fields and were greater in swamp than in white-moss soil.

The chemical composition of the hay from the two soils also differed. The swamp hay contained more potassium, phosphorus, and nitrogen than the white-moss soil hay, both on fertilized and unfertilized plats. The lime content was greater in the hay from the limed white-moss soil.

White-moss soil, when completely fertilized, became enriched in potash and phosphoric acid but lost nitrogen in the drainage water. Swamp soil, when completely fertilized, retained phosphoric acid but lost potash and nitrogen. The percentage composition of the soil was, however, but little affected.

Calcium, magnesium, potassium, and sodium in the drainage water from limed and unlimed soil, T. L. Lyon and J. A. Bizzell (Jour. Amer. Soc. Agron., 8 (1916), No. 2, pp. 81-87).—Experiments conducted at Cornell University with limed and unlimed clay-loam soil, growing corn, oats, wheat, timothy, and clover, are reported, in which the drainage water resulting from natural rainfall was analyzed twice yearly for five years.

It was found that "of the bases, calcium, magnesium, sodium, and potassium, the last named is most firmly held in the soil used. . . . An application of burned lime corresponding to the lime requirement of the surface foot of soil was not accompanied by any appreciable increase in the quantity of potassium present in the drainage water, [and] did not result in any greater quantity of potassium in the crops raised on the limed soil than in those that grew on the soil that received no lime. So far as could be ascertained . . . there was no liberation of potassium effected by the lime treatment. Magnesium was the only one of the four bases that appeared in larger quantity in the drainage from the limed than from the unlimed soil. The calcium-magnesium ratio is much broader in the drainage water from this soil than in the soil itself. The effect of an annual application of potassium sulphate at the rate of 200 lbs. per acre was to increase materially the quantity of calcium and magnesium in the drainage water, but not to increase the quantity of potassium. The sum total quantity of the bases calcium, magnesium, potassium, and sodium was less in the drainage water of the soil that received an application of lime than in the water from the unlimed soil."

The loss of sulphur in drainage water, T. L. Lyon and J. A. BIZZELL (Jour. Amer. Soc. Agron., 8 (1916), No. 2, pp. 88-91).—Experiments conducted at Cornell University on a clay loam soil growing five crops, in which the drainage water for four years was analyzed for sulphates, are reported.

It was found that "the sulphur removed in the drainage water from an unplanted, unlimed soil that had received some farm manure but no commercial fertilizer amounted to 44 lbs. per acre annually. The application of lime increased the quantity of sulphur removed by the drainage water. Soil on which crops were grown lost less sulphur in the drainage water than did unplanted soil when otherwise similarly treated. The annual application of sulphate of potash at the rate of 200 lbs. per acre markedly increased the quantity of sulphur in the drainage water. From one-half to two-thirds of the sulphur applied annually as sulphate of potash was removed in the drainage water."

Physicochemical studies of soils.—IV, The cause of the fixation of phosphoric acid by the soil, U. Pratolorgo (Staz. Sper. Agr. Ital., 48 (1915), Nos. 5-7, pp. 457-490. figs. 2; abs. in Chem. Zentbl., 1915, II, No. 17, p. 917).—Continuing previous work (E. S. R., 35, p. 21). experiments with loose alluvial soils, alluvial clay, humus soil, and calcareous clay soils and monobasic phosphates are reported. The results are taken to indicate that the fixation of phosphoric acid can be attributed to absorption processes by positively charged soil colloids, mainly the hydroxids of iron, aluminum, and manganese, and also to chemical fixation by calcium salts.

The oxidizing power of soils, F. C. GERRETSEN (Arch. Suikerindus. Nederland. Indië, 23 (1915), No. 21, pp. 833-847, figs. 2; Meded. Proefstat. Java-Suikerindus., 5 (1915), No. 11, pp. 317-331, figs. 2; abs. in Chem. Abs., 10 (1916), No. 4, p. 503; Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1583, 1584; Jour. Soc. Chem. Indus., 35 (1916), No. 6, p. 372).—In tests with 19 cane soils having normal oxidizing power, it was found that when tested before and after sterilization the amount of iodin liberated by the soils from 1 per cent potassium iodid solution decreased noticeably. This is taken to indicate that "in case soils have an oxidizing power it is at least partly due to oxidases." In six cases where the stand of cane was good from 120 to 354 mg. of iodin were liberated by 100 gm. of soil; in three cases where the stand was fair to moderately poor from 79 to 184 mg. were liberated; and in eleven cases where the stand was bad there was no iodin liberated in eight cases and up to 47 mg. in the others. "The amount of gaseous oxygen necessary to liberate the average amount of iodin would amount to 30 to 100 per cent of the pore space in a heavy clay soil. Hence it is concluded that the poor stand of cane on strongly reducing soils is due to lack of oxygen at the root tip."

A method of determining the oxidizing power of soil by means of potassium iodid solution is described.

The principles of crop production, E. J. Russell (Jour. Chem. Soc. [London], 107 (1915), No. 638, pp. 1838-1858, pl. 1, figs. 9; abs. in Nature [London], 96 (1916), No. 2412, pp. 579-583, figs. 4).—This is a brief review of work by the author and others in which the main factors influencing crop production are discussed, special attention being drawn to the so-called limiting factor.

Soil survey of Walker County, Alabama, J. O. Veatch, A. M. O'Neal, Jr., and J. F. Stroud (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 30, fig. 1, map 1).—This survey, made in cooperation with the State of Alabama and issued July 31, 1916, deals with the soils of an area of 510,720 acres in northwestern Alabama, the surface of which is prevailingly undulating to hilly, with small areas of extremely rough and broken country.

"The soils of the greater part of the county are residual in origin, and are derived from shales and fine-grained sandstones. The silt loam and fine sandy loam types of soil predominate. The soils are generally well drained and easily tilled." Exclusive of steep broken land, 12 soil types of 8, series are mapped, of which the Dekalb very fine sandy loam, shale loam, and silt loam, and the

Hanceville silt loam cover 27.3, 21.5, 11, and 14.3 per cent of the area, respectively.

Soil survey of Pennington County, Minnesota, W. G. SMITH, N. M. KIRK, and F. Ward (U. S. Dept. Agr., Advance Shects Field Operations Bur. Soils, 1914, pp. 28, pl. 1, fig. 1).—This survey issued July 15, 1916, deals with the soils of an area of 388,480 acres in northwestern Minnesota, the surface of which is mainly level to undulating, with a general slope toward the southwest. "The natural drainage of the county is for the most part poor and must be assisted by artificial means."

The soils of the county are of glacial origin. Including peat, 9 soil types of 3 series are mapped, of which the Fargo clay loam, Fargo loam, peat, and Benoit loam cover 36.4, 17.3, 17.1, and 14.5 per cent of the area, respectively.

The chemical composition of some Minnesota peat soils, Def. Hungerford (Jour. Amer. Peat Soc., 9 (1916), No. 2, pp. 74-81).—Analyses made at the Minnesota Experiment Station of 28 samples of peat, 10 of which were from the muskeg type and 18 from the grass peat, are reported and discussed.

The mustleg peat, in general, contained a higher percentage of volatile matter than the grass peat, this averaging 86.84 per cent in the former and 73.71 per cent in the latter. The nitrogen content was higher in the grass than in the muskeg peats, the former containing an average of 1.874 per cent and the latter of 2.569 per cent. The percentages of both phosphoric acid and potash were also somewhat higher in the grass than in the muskeg peats.

The greatest difference in composition between the muskeg and the grass peat was found in their lime content, although there was considerable variation in the amount present in different samples of both types. The muskeg contained on the average 1.237 per cent of lime, but different samples varied from 0.25 per cent to 5.97 per cent. The grass peat contained 3.35 per cent as an average, and varied from 1.03 to 14.36 per cent.

The analysis is taken to indicate that Minnesota peat soils resemble but do not agree exactly in composition with those of European countries.

The soils of Mississippi, W. N. Logan (Mississippi Sta. Tech. Bul. 7 (1916), pp. 84, pl. 1, figs. 15).—This is a revision and an enlargement of Technical Bulletin 4 of the station (E. S. R., 29, p. 416), to which a brief discussion of the general properties of soil and chapters on soil acidity and its correction and on geological formations from which the soils were derived have been added.

Soil survey of Dunklin County, Missouri, A. T. Sweet, B. W. Tillman, H. H. Krusekopf, C. E. Deardorff, W. I. Watkins, and E. W. Knoble (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 47, pls. 3, fig. 1, map 1).—This survey, made in cooperation with the Missouri Experiment Station and issued August 8, 1916, deals with the soils of an area of 343.040 acres in southeastern Missouri which consists topographically of hill lands, bench lands, including sandy ridges and glade lands, and low bottom lands subject to overflow.

"Nearly all parts of Dunklin County have been drained directly or at least greatly benefited through the drainage of low-lying adjacent areas. . . . The most important soils . . . are the sandy terrace or 'sand-ridge' soils."

Twenty-four soil types of nine series are mapped, of which the Sharkey clay and the Lintonia fine sandy loam and fine sand cover 21.1, 15.2, and 14.8 per cent of the area, respectively.

Soil survey of Roger Mills County, Oklahoma, J. A. Kerr, J. H. Agee, and E. C. Hall (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 32, fig. 1, map 1).—This survey, issued July 11, 1916, deals with the soils of an area of 726,400 acres in the Great Plains region in western Oklahoma.

The surface consists of a high rolling plain, deeply dissected by flowing streams. The topography of the plain is undulating to gently rolling, while that of the lowland is hilly. Including rough broken land and dune sand, 22 soil types of eight series are mapped, of which the Vernon clay loam and very fine sandy loam cover 19 and 9.2 per cent of the area, respectively, rough broken land 11.8, and the Richfield fine sandy loam 10.1 per cent.

Soil survey of Lancaster County, Pennsylvania, B. D. Gilbert, W. B. Cobb, E. L. Moffitt, and J. F. Cox (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 70, fig. 1, map 1).—This survey, made in cooperation with the Pennsylvania College and Station and issued July 21, 1916, deals with the soils of an area of 602,240 acres in southeastern Pennsylvania which "consists of a central valley or lowland occupying about 50 per cent of its total area, surrounded on all sides by highland, except where narrow belts of the lowland project from the main area and extend to or beyond the county line." The regional drainage is mature and complete.

The soils of the county are residual and alluvial in origin and the loams and silt loams predominate, including rough stony land and meadow. Thirty-six soil types of 17 series are mapped, of which the Hagerstown silt loam and the Manor loam cover 24 and 20.6 per cent of the area, respectively.

Soil survey of Brazos County, Texas, J. O. Veatch and C. S. Waldrop (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 53, fig. 1, map 1).—This survey, made in cooperation with the Texas Experiment Station and issued July 10, 1916, deals with the soils of an area of 369,920 acres in east-central Texas lying in the Gulf Coastal Plain. The topography is level to gently rolling and the greater part of the county is well drained.

The county "embraces a rather wide range of soils, having peculiar differences in texture, structure, drainage, or other characteristics, which . . . affect in some degree crop yields and the ease or difficulty of cultivation. . . . Two general groups are recognized, (1) the upland soils and (2) the bottom land and terrace soils. The upland soils are mainly derived from underlying sedimentary deposits. The bottom and terrace soils are alluvial." Thirty soil types of 13 series are mapped, of which the Lufkin and Susquehanna fine sandy loams cover 40.3 and 11.3 per cent of the area, respectively.

Soil bacteriology, C. M. Hutchinson (Rpt. Agr. Research Inst. and Col. Pusa, 1914–15, pp. 79–89; Ann. Rpt. Bd. Sci. Advice India, 1914–15, pp. 110–116).—Continuing work previously reported (E. S. R., 33, p. 513), it was found in studies of bacteriotoxins in soils that "the inhibition of nitrification occurring in soils under water-logged or semianaerobic conditions was not due merely to lack of oxygen required for formation of the completely oxidized product, but to the action of toxins resulting from the activity of certain classes of bacteria which rapidly multiply under these conditions. . . . It was found that such toxins result from decomposition of organic nitrogen compounds by bacterial action under semianaerobic conditions, and further proof that the inhibition of nitrification is not due merely to shortage of oxygen was afforded by the observation that, with the same air supply as was sufficient for complete nitrification of ammonium sulphate in soil, nitrification of oil cake containing the same amount of nitrogen was completely inhibited. . . .

"It was found in actual practice in the field that germination in a soil which had been water-logged was interfered with and that the ensuing crop was consequently poor, nor was this remedied by application of nitrate of soda, although the use of superphosphate was successful. Laboratory experiments showed that rapid reduction of nitrate takes place in water-logged soil, a large proportion of nitrite being formed. . . . It was found in the laboratory that superphosphate

had a neutralizing action upon the toxicity to bacteria of extracts of certain soils, and this was traced to the free acid. . . .

"Ammonification proceeded at the normal rate in soil under semianaerobic conditions and was apparently not interfered with by the bacteriotoxins produced, although the activity of such ammonifiers as *Bacillus mycoides* is actually lowered by the presence of B. X. This latter organism does not appear to be universally present in soils. No concentration of ammonia above that in the aerated control was found, nor was this gas given off by the anaerobic soil."

In a special experiment to test the action of the carbon dioxid formed in soil by bacterial action upon nitrification in that soil, it was found that "under partially anaerobic conditions absorption of the carbon dioxid produced no effect upon nitrification in soil, either of oil cake or of ammonium sulphate... Complete nitrification of ammonium sulphate took place under semianaerobic conditions in which no nitrification of oil cake occurred....

"It was found that salts of some of the heavy metals, such as copper, had a decided influence in neutralizing the toxic action toward seedlings of extracts of soils kept under anaerobic conditions."

In studies of nitrification "grass has been found to prevent entirely accumulation of nitrate in the soil in which it is growing.... The optimum amount of organic matter as oil cake containing 5 per cent of nitrogen for nitrification in Pusa soil was found to be about 1 per cent of soil weight.... The effect of temperature on nitrification in Pusa soil was tested, the optimum being found to be near 35° C. (95° F.). No nitrate was formed at 40°, nor did nitrification take place in soil which had been kept at 40°, when its temperature was afterwards reduced to 30°."

Experiments to determine the cause of the rise and sudden fall of the rate of carbon dioxid evolution when solid bacterial foodstuffs are added to live soil indicated that this result "was due in part to auto-intoxication by the soil bacteria and in part to the purely physical facts of the case."

The progress of green-manuring experiments and studies of Azotobacter, to be reported on elsewhere later, is also noted.

The humification of the constituents of plant organisms and the effect of natural agents upon it, A. Trusov (Trouseff) (Selsk. Khoz. i Læsov., 247 (1915), Apr., pp. 575-605; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 11, pp. 1453, 1454).—Separate studies of the processes of decomposition of the different constituents of plant organisms and of various mixtures of these constituents, including carbohydrates with proteins, fats, pigments, tannic and encrusting bodies, gums, glucosids, and organic acids, are reported in an effort to throw light on the genesis of humus. Decomposition was studied both as it occurs on the soil surface and within the soil.

It was found that "lignin, proteins, starch, chlorophyll, tannic bodies, phlobaphenes, some fats, and gums are the direct sources of the humus formed from plant residues on the surface of the soil. Cellulose, hemicellulose, monosaccharids and disaccharids, glucosids, and organic acids (including amidoacids) do not give rise to humus under these circumstances. In view of the considerable amount of proteins contained in bacteria, the possibility of the transformation of the bodies of bacteria into humus may be admitted. In the case of fungi this transformation has been confirmed. . . .

"All the organic constituents utilized by micro-organisms for their nutrition may, by means of their bodies containing nitrogen, become indirect sources of humus. Typical black humus is rapidly formed only when all of the following constituents together take part in its formation: Lignin, proteins, pigments,

and tannins. In a greater length of time it may also be formed by the mixture of lignin and proteins and also by the latter alone. A certain correlation is observed between the artificial and the natural formation of humus, in that in natural surroundings humification is restricted to those organic bodies which readily undergo a similar transformation under the influence of very active chemical agents. Humus can not be always identical in its chemical composition, but must contain the decomposition products of lignin, proteins, pigments, tannic substances, etc."

Humus acids in the light of the results of recent investigations, E. Gully (Internat. Mitt. Bodenk., 5 (1915), Nos. 3, pp. 232-247; 4, pp. 347-368; abs. in Ztschr. Angew. Chem., 28 (1915), No. 77, Referatenteil, p. 487).—The author reviews the work of others bearing on the subject and reports the results of new experiments on the degree of acidity of different substances, including dopplerite and beech leaves.

A comparison of the acidity of the substances before and after extraction of the bases showed evidences of the action of colloids. The results are taken to indicate that all plants contribute to the acidity of humus. No direct relation was found between the acid content of moor substances and the process of peat formation. The acidity stood in inverse proportion to the plant food content. The natural humus acids were found to form neither soluble alkali nor insoluble lime salts. It is thought that the previously formed humus acids in living sphagnum are identical with the so-called humus acids.

Report on experiments with bacterized peat or humogen, F. J. CHITTENDEN (Jour. Roy. Hort. Soc., 41 (1915), No. 2, pp. 305-326, figs. 2).—Five series of pot and plat experiments are reported. The purpose was to determine the influence of additions of bacterized peat on the growth of various flowers and vegetables.

It was found that plant growth was greatly and uniformly increased by bacterized peat in the indoor pot experiments, in which the material was used at rates of 1 part of peat to 1, 3, and 7 parts of soil and the soil was watered with a bacterized peat extract. Much less favorable results were obtained in the outdoor plat experiments. In comparative lots 20 tons of barnyard manure per acre gave better results than 1 ton of bacterized peat. The full results were obtained from the use of peat only when the supply of water was abundant. "The results on the whole show that when prepared under the best conditions bacterized peat is capable of acting as a very effective manure."

The effects of radio-active ores and residues on plant life, M. H. F. Sutton (Reading, Eng.: Sutton & Sons, 1915, Bul. 7, pp. 20, figs. 9).—This is a report of a second series of experiments conducted during 1915, in which the results of the 1914 experiments (E. S. R., 34, p. 821) are reviewed and the results obtained with nine different radio-active materials when used on tomatoes, potatoes, radishes, lettuce, onions, carrots, vegetable marrows, and spinach beets, and on fruit, roots, foliage, and bulbs are reported.

"The experiments indicate no more hope of the successful employment of radium as an aid to either horticulture or agriculture than did the trials carried out in 1914." It is considered conclusive that the farmer and gardener need look for no material benefit from radium, the chief result having been to emphasize the value of barnyard manure and complete artificial fertilizers.

Experiments with green manures and green manuring on sandy and white moss soils at Flahult, H. von Feilitzen (Svenska Mosskulturför. Tidskr., 29 (1915), No. 4-5, pp. 326-338, figs. 3).—Experiments on the reclamation of sandy and white moss soils deficient in plant food, especially nitrogen, and having a low moisture retaining capacity are reported. The rotation included rye, potatoes, carrots, and different legumes.

Blue lupines gave the most favorable results, being better than yellow lupines. Alfalfa appeared to be a failure as a green manure on these soils. The data from several years' experiments are reported in tabular form.

The displacement by water of the nitrogenous and mineral material contained in leaves, G. André (Bul. Soc. Chim. France, 4. ser., 17 (1915), No. 23, pp. 429-441; abs. in Chem. Abs., 10 (1916), No. 6, p. 796).—Experiments with chestnut leaves are reported.

Analyses of 100 leaves on October 17 and of 100 more on the following April 21, which had wintered on the ground, showed a loss of 7.5 per cent of the nitrogen, 67.4 per cent of the phosphoric acid, and 87.7 per cent of the potash. Dead leaves after wintering in piles on the ground were found to contain about twice as much nitrogen and about the same amount of phosphoric acid as a good farm manure. The nitrogen did not nitrify as readily as that of manure.

To determine the influence of water alone, leaves were covered with water together with a few drops of formalin. The solution was decanted, replaced by more water, and the solutions analyzed. The last portion, after 255 days extraction, contained 6.27 per cent of the total nitrogen, 74.14 per cent of the total phosphoric acid, and 94.58 per cent of the potash. This is taken to indicate that the nitrogen of the leaves exists as a protein which does not readily hydrolyze. It was further observed that the younger the leaf, the larger were the percentages of nitrogen, phosphoric acid, and potash extracted in the first week.

The same experiments were conducted with reference to sulphur, lime, and magnesia content. After immersion for one month in water it was found that .56.8 per cent of the total sulphur, 50.72 per cent of the magnesia, and only 20.03 per cent of the lime were displaced.

Report on ten years' experiments with sewage fertilizers, Kuhnert (Mitt. Deut. Landw. Gesell., 31 (1916), No. 16, pp. 253-258).—Field experiments on several different German experimental fields of swampy sand soil with cabbages, rye, oats, potatoes, and clover to determine the fertilizing value of stable manure, peat and sewage mixture, and soil and sewage mixture when applied in amounts of about 22 tons, 18 tons, and 13 tons per acre are reported. The peat and sewage mixture used in one case contained 0.44 per cent total nitrogen, 0.23 per cent water-soluble phosphoric acid, and 0.35 per cent potash; and in a second case 0.65 per cent total nitrogen, 0.28 per cent water-soluble phosphoric acid, and 0.31 per cent potash. The soil and sewage mixture used contained 0.39 per cent total nitrogen, 0.01 per cent soluble phosphoric acid, and 0.14 per cent potash.

In all cases the plats treated with sewage fertilizers produced an increase in crop over the unfertilized plats, in some cases exceeded the plats fertilized with stable manure, and gave on the average as good results as plats receiving complete artificial fertilization. It is considered inadvisable and unprofitable to use raw sewage for a fertilizer. Mixing with peat or earth in amounts double the amounts of sewage used was found to be a better practice.

Solubility of plant-food elements as modified by fertilizers, C. A. Jensen (Jour. Amer. Soc. Agron., 8 (1916), No. 2, pp. 100-105).—Continuing previous work (E. S. R., 35, p. 321), experiments on a field of sandy loam soil, supporting a growth of sugar beets but which had previously been in alfalfa for several years are reported, showing the seasonal changes in the water-soluble nutritive constituents in the soil and the effect of fertilizers on the amounts of the various elements recovered. The fertilizers were applied at the following rates per acre: "Nothing; nitrate of soda, 300 lbs. at time of planting and 300 lbs. when the beets were thinned; calcium cyanamid, 500 lbs.; superphosphate, 500 lbs.; bone meal, 500 lbs.; factory waste lime, 15 tons; composted manure, 14

tons; ordinary dry yard manure, 14 tons; and yard manure, 14 tons plus 300 lbs. ammonium sulphate."

It was found that "the plats receiving composted manure showed nearly twice as much water-soluble potash in the surface foot as any of the other plats. The seasonal averages of this element were not influenced by any other fertilizer treatment. There was a general decrease in the quantity of water-soluble potash from the middle of May till about the middle of July. After that time, the quantity increased to approximately the amount found earlier in the season.

"Plats receiving nitrate, superphosphate, and composted manure all showed less water-soluble phosphoric acid than the checks. None of the fertilizer treatments resulted in a marked increase in water-soluble phosphates, though cyanamid, bone meal, and manure plus ammonium sulphate caused a small increase. The variation in water-soluble phosphorus from week to week was less than that of any other element measured.

"Taking account of the sulphur added in the various fertilizers, none of the treatments apparently had any marked influence in rendering the sulphates in the soil more soluble in water. There was a decrease in the amount of soluble sulphates from the early part of the season till the latter part of July, corresponding in general to the seasonal decrease in soluble potash.

"The amounts of water-soluble manganese were very small and disappeared entirely after the middle of June. The plats receiving nitrate, composted manure, waste lime, and manure plus ammonium sulphate, showed the highest manganese content. It is remarked . . . that the sugar beets grown on plats showing the highest amounts of water-soluble manganese and sulphur gave the highest yields and the most sugar per acre."

New experiments on the action of lime nitrogen, A. STUTZER and W. HAUPT (Jour. Landw., 63 (1915), No. 4, pp. 385-387).—Pot experiments with oats and white mustard on soil consisting of equal parts of loam and quartz sand are reported, the purpose of which was to determine the fertilizing value of the nitrogen compounds of lime nitrogen which were insoluble in water. The residue resulting from treatment of lime nitrogen with an excess of water and with sufficient hydrochloric acid to produce an acid reaction in the solution was used. One kg. of lime nitrogen yielded 24.1 gm. of insoluble residue containing about 7 per cent of nitrogen. This was used in amounts equivalent to 0.8 gm. of nitrogen per pot.

It was found that the nitrogen was well utilized by mustard, the utilization in one case being unexpectedly high. The same results were obtained with oats. These results are taken to indicate that this part of the lime nitrogen does not decrease crop yield.

Accumulated fertility in grass land in consequence of phosphatic manuring, II, W. Somedulle (Jour. Bd. Agr. [London], 22 (1916), No. 12, pp. 1201–1209, pl. 1).—In a second report on these experiments (E. S. R., 32, p. 331), it was found that "when basic slag is used on grass land the increase of herbage, or of meat or milk, does not represent the whole of the benefits. Concurrently with such increase there is improvement in the fertility of the soil. . . The extent of the accumulation of fertility depends on the amount of slag used, on the period of time during which it acts, and on the way in which the land responds to it. . . The fertility that is accumulated seems to be largely due to nitrogen stored up by leguminous plants, though increase in nonleguminous humus is probably not without influence. Residues of slag appear also to play some small part in the result."

The action of potash fertilization on the water requirements of plants and on the water content of soil, C. von Seelhobst (*Jour. Landw.*, 63 (1915), No. 4, pp. 345-356).—The work of others bearing on the subject is reviewed and

pot experiments, in which 1 gm. each of kainit and a 40 per cent potash salt were added to 100 gm. of soil, are reported.

The results obtained by others and the original experimental results are taken to indicate that potash fertilization decreases the water requirement of plants. Potash fertilization with kainit on a large scale, however, does not increase the moisture content of soil in the summer months, since the moisture absorbed from moist air by the hygroscopic salt is again evaporated from the soil into dry air.

The hygroscopicity of various potassium fertilizer salts, H. von Feilitzen (Svenska Mosskulturför. Tidskr., 29 (1915), No. 4-5, pp. 382-401, figs. 3).—Experiments with kainit and 20, 37, and 40 per cent potassium salts are reported.

Kainit and the 20 and 37 per cent salts, after storage from three to six months in sacks, contained a few lumps, and the 40 per cent salt contained a few lumps not passing the 4 mm. sieve. After nine months' storage in sacks, kainit was damp at the top and quite wet at the bottom. It formed one lump which was, however, dry. The same was observed with the 20 per cent salt. The 37 per cent salt stood in small damp lumps. The 40 per cent salt stood in even smaller lumps, but was all damp. In all cases the sacks were wet and had to be cut open.

Tests of the availability of different grades of ground limestone, L. B. Broughton, R. C. Williams, and G. S. Frazer (Maryland Sta. Bul. 193 (1916), pp. 31–45).—Experiments on the solubility of limestone and oyster shells of different grades of fineness in water and water charged with carbon dioxid and in a soil solution, and experiments on  $\frac{1}{20}$ -acre plats of sandy loam soil to determine the influence of different sizes of ground limestone and oyster shells on wheat and crimson clover, are reported.

It was found that "ground limestone and oyster shells of different degrees of fineness vary in their degree of solubility in water and water charged with carbon dioxid [and in soil solution] according to the fineness of the material. . . . In order to furnish as much soluble calcium, by the use of ground stone or ground shells to a soil as calcium oxid will furnish, the stone or shells must be ground so that at least 90 per cent will pass an 80-mesh sieve. . . . Ground limestone, when ground to pass an 80-mesh sieve, gives yields equal to and sometimes greater than calcium oxid."

It is concluded that "better results will be obtained by using calcium oxid (lime) or limestone and oyster shells ground to pass an 80-mesh sieve than by using a coarser grade of limestone or shells. However, marked increases will be noted by the use of large quantities of coarse material, due in a large measure to the fine material that is found in any limestone after it has been ground."

Tabulated analyses of commercial fertilizers, W. Frear (*Penn. Dept. Agr. Bul. 277 (1916)*, pp. 55).—This bulletin contains the results of actual and guarantied analyses and estimated valuations of 371 samples of fertilizers and fertilizing materials collected for inspection in Pennsylvania from August 1 to December 31, 1915.

[List of fertilizer and lime manufacturers and importers and their products] (Penn. Dept. Agr. Bul. 275 (1916), pp. 42).—This bulletin contains a list of 184 fertilizer and lime manufacturers and importers and licensed brands of their products, together with the text of the Pennsylvania fertilizer law.

The international movement of fertilizers and chemical products useful to agriculture (Internat. Inst. Agr. Rome, Internat. Crop Rpt. and Agr. Statis. 7 (1916), No. 3, pp. 177-221).—This review, issued in March, 1916, is the fourth of a series (E. S. R., 34, p. 426) and gives figures for the fertilizer production and trade for 1913, 1914, and 1915. Data are also given for imports and exports of sulphur for the different countries and for the production of copper

sulphate in Europe and North America. No figures are given relating to the production of potash salts in Germany, the tables showing only those amounts delivered for internal trade and export as fixed by the law of 1910.

The wholesale prices of raw phosphate remained practically unchanged in the United States during the seven months ended with February, 1915 (prices are not given for superphosphates). Prices of potash salts were prohibitive from the standpoint of their use as fertilizers during the half year ended with January, 1916. There was a steady increase in the price of sodium nitrate during the same period. Prices of ammonium sulphate fluctuated, but were substantially the same at the end as at the beginning of the half year.

A bibliography of 445 references to recent literature on the subject of fertilizers is appended.

## AGRICULTURAL BOTANY.

Annual periodicity in plants, G. I.Akon (Naturw. Ztschr. Forst u. Landw., 13 (1915), No. 2-3, pp. 85-101).—From investigations discussed the author concludes that an inherent annual periodicity in woody plants does not exist as such, but that this, as seen in nature, is the result rather of external influences on the tree. The plant is claimed to have the capability to grow continuously under certain conditions, or under other conditions to experience a resting period.

Rhythmic alternation of growth and rest in plants, G. Lakon (Biol. Centbl., 35 (1915), No. 10, pp. 401-471).—The article above noted has been followed up with a more extended discussion and bibliography. The evidence is claimed to support the conclusion that the development of periodicity, like that of the plant itself, is dependent principally upon the occurrence of external conditions favorable thereto.

Energy transformations during the germination of wheat grains, Lucie C. Doyer (K. Akad. Wetensch. Amsterdam, Proc. Sect. Sci., 17 (1914), pt. 1, pp. 62-70).—From investigations on germinating wheat, the author has concluded that the loss of energy and evolution of heat both show a great increase during the germination of wheat grains, especially about the third day. The evolution of heat depends greatly on the surrounding temperature, the optimum being about 35° C. (95° F.). The total loss of energy during germination at 20° exceeds the loss of energy by evolution of heat at the same temperature.

The influence of frost and light on the germination of seeds, W. KINZEL (Naturw. Ztschr. Forst u. Landw., 13 (1915), No. 10, pp. 433-468).—Later results are given of experimentation previously noted (E. S. R., 33, p. 343) testing influences bearing on germination, particularly the effect of frost and light as shown by representatives of a large number of plant families, together with a bibliography of the subject.

Germination as related to illumination, E. Lehmann (Ztschr. Bot., 7 (1915), No. 9, pp. 560-580).—The author has followed up the contribution of Gassner (E. S. R., 35, p. 524), with a critical review of recent literature on the relation of light to germination. Some experimental data in tabular form obtained recently by Ottenwälder in connection with the author are included.

On the mutual influence of phototropic and geotropic reactions in plants, C. E. B. Bremeram (K. Akad. Wetensch. Amsterdam, Versl. Wis en Natuurk. Afdeel., 23 (1914–15), pt. 2, pp. 1241–1255; also in ditto, Proc. Sect. Sci., 17 (1914–15), pt. 2, pp. 1278–1291).—The tests here described refer to the summation of phototropic and geotropic curvatures, changes in the phototropic and geotropic reactions under the influence of light, and changes in the geotropic and phototropic reactions under the influence of gravity.

It is stated that the reactions of Avena to gravitational stimuli and to light stimulation of small intensity do not noticeably influence each other. By varying the duration and the intensity of illumination, modifications were produced; namely, the reversal of the direction of curvature and a change in the rate of reaction.

Determination of cell sap concentration by the freezing point method, G. J. Bouyoucos and M. M. McCool (Jour. Amer. Soc. Agron., 8 (1916), No. 1, p. 50).—In the present brief note attention is called to the fact that as a result of the successful application of the freezing-point method in a study previously reported (E. S. R., 34, p. 721), this method can now be employed to investigate many other problems. It is stated that the determination of the concentration of the plant cell sap can be accomplished directly in the plant without extracting it by crushing the plant tissue, placing it in the freezing tube, inserting the thermometer, and following the procedure described. The results of the considerable work already done have fulfilled anticipations, inasmuch as the concentration of the cell sap is greater when determined directly in the plant than after extraction.

The transpiration coefficients of cultivated plants, N. Tulaikov (Toulaïkoff) (Zhur. Opytn. Agron., 16 (1915), No. 1, pp. 36-76, figs. 4; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 6, pp. 813-815).—This is an account of the study at the Besentchuk Agricultural Experiment Station during 1910 to 1914, in the culture house and in the open, of the transpiration coefficient or the amount of water necessary to form a unit of dry matter.

The results, which are tabulated, are considered to show that the variations of the transpiration coefficient of a given plant are sometimes larger in different years than for different species in the same year. The numerical coefficient in the open was about twice as large as that in the culture house, but its volume depends upon meteorological conditions in the same way as in the former case. Early sowing gives a large crop and a low transpiration coefficient, late sowing a high transpiration coefficient but a lessened grop. The coefficients of wheat and oats in rows are lower than in the same crops sown broadcast. In 1914 the largest crops of summer wheat and oats corresponded to the lowest water consumption.

Assimilation of carbon dioxid by plants, P. N. RAIKOW (Chem. Ztg., 39 (1915), No. 105, pp. 657-659; abs. in Jour. Chem. Soc. [London], 108 (1915), No. 637, I, pp. 1047, 1048).—A theory herein set forth intended to explain the assimilation of carbon dioxid by plants is based largely on the properties of chlorophyll and the presence of an oxonium compound. According to this view, the oxygen liberated is probably derived one-half from carbon dioxid and one-half from water.

Importance of glycogen and starch as intermediate products in the transformations induced by certain organisms, H. I. WATERMAN (Chem. Weekbl., 12 (1915). No. 24, pp. 552-556; abs. in Jour. Chem. Soc. [London], 108 (1915), No. 633, I, p. 630).—Details are given of an investigation of the percentages of invert sugar, sucrose, and starch present in bananas dried at temperatures between 45° and 105° C.

Recent studies on the chemical and histological characters of radish cultivated in the presence of sugar, M. Molliard (Rev. Gén. Bot., 27 (1915), No. 318, pp. 161-168, pls. 2, figs. 2).—Studies pursuant to those previously reported (E. S. R., 19, p. 932), employing sugar solutions of different strengths, show resulting alterations, which are described, in tissue structure and cell content.

The relation between amylase and sugar content in resting potato tubers, J. Bodnár (Kisérlet. Közlem., 18 (1915), No. 4, pp. 788-795, No. 1).—This work is said to have shown the presence of maltase in resting potato tubers. The activity of amylase in resting tubers shows a correspondence with the presence of nonreducing and total sugars, certain exceptions being noted. It is stated that tubers which possess amylase of high activity either produce much sugar or exhibit intensive respiration.

Zymase and carboxylase in potato and sugar beet, J. Bodnár (Bot. Közlem. [Budapest], 14 (1915), No. 3-4, pp. 122-124; abs. in Bot. Centbl., 129 (1915), No. 23, pp. 597, 598).—From potato tubers and beet roots the author was able to obtain zymase in stable and active condition. In its presence the bacteria in diseased plants changed alcohol to acetic acid.

Oxidation of alcohol by seedlings, W. Zaleski (Biochem. Ztschr., 69 (1915), No. 3-4, pp. 289-293; abs. in Jour. Chem. Soc. [London], 108 (1915), No. 633, I, p. 630).—In pursuance of former work (E. S. R., 28. p. 428), the author reports the results of his recent studies on cereal and legume seedlings. This is claimed to support the view that alcohol is oxidized in the growth of these seedlings under the conditions here employed. It is not claimed, however, to have been shown that alcohol is a normal intermediate product of plant metabolism.

Protein transformations in yeast.—II, Influence of the medium on protein formation, W. Zaleski and W. Schataloff (Biochem. Ztschr., 69 (1915), No. 3-4, pp. 294-304).—Information given previously (E. S. R., 31, p. 223), regarding the influence of aldehyde on post-mortem changes in yeast has been followed up with a detailed account of studies on the effects in this connection of alcohols and phenols, of the relation of the medium, and of the influence exerted by other substances. Some of the work is still in progress and caution is suggested regarding broad generalizations in this connection.

The influence of nitrates on the development of root tubercles, A. J. EWARF (Jour. Dept. Agr. Victoria, 13 (1915), No. 12, pp. 759, 760).—In order to test the statement, frequently made, that the addition of soluble nitrates to the soil decreases by a kind of compensatory action the formation of root tubercles by legumes, experiments were carried out with Vicia faba in double and in single rows, employing sodium and potassium nitrates. Allowing for vitiation of the results by heavy rainfall in case of the double rows, it is concluded that although the nitrates used did not appreciably diminish the formation of root tubercles, their use as manures in the case in question would have been highly unprofitable, the plants being able to gain all the nitrogen they required from supplies already present in the soil.

The influence of manganese on the growth and ash composition of potato, S. Sijfert (Věstnik 5, Sjez. Čes. Lék. Přír., 1915, p. 411; abs. in Bot. Centbl., 129 (1915), No. 15, pp. 376, 377).—It is stated that the use of manganese results in an increase of the potato crop and in the nitrogen content thereof, but in a decrease of starch. Though sulphates were present in the fertilizer, very little sulphur trioxid was to be found in the ash.

The occurrence of hematoid iron compounds in plants, I, II, G. Gola (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 12, pp. 1239-1243; II, No. 6, pp. 289-294).—Organic compounds of iron were found so generally distributed in very diverse groups of plants as to suggest their universal occurrence in this connection. The necessity for more intimate study of the part played by iron in the physiology of respiration is suggested.

635

Chondriosomes in fungi and algæ, A. Guilliermond (Rev. Gén. Bot., 27 (1915), Nos. 319, pp. 193-207, pls. 2, fig. 1; 320, pp. 236-253, pls. 2; 321, pp. 271-288, pls. 3, fig. 1; 322, pp. 297-315, figs. 2).—Continuing work previously noted (E. S. R., 32, p. 524), the author states that chondriosomes have been found in a large number of fungi, in which they appear to be generally present. In some algæ it was impossible to demonstrate their presence, but the chloroplast, which is here highly differentiated, shows some chemical and histological characters proper to mitochondria and may consist of fine fibrillar mitochondrial substance, as physiologically it seems to play the rôle appropriate thereto and may be considered as a sort of mitochondrial reticulum. In the Cyanophyceæ the chondriosome, as such, appears to be completely wanting, but it appears to be more or less completely replaced functionally by the nucleus. The physiological rôle of the chondriosome appears clearly evident in case of fungi, as they produce vesicles which are claimed to be absolutely analogous to those which produce starch in the higher plants.

The bibliography appended includes titles of 19 contributions by the author.

Division in mitochondria and their relations with the phenomena of secretion, F. Moreau (Compt. Rend. Soc. Biol. [Paris], 78 (1915), No. 6, pp. 143, 144; abs. in Bot. Centbl., 129 (1915), No. 23, pp. 593, 594).—Considering the three views regarding the origin of mitochondria which are more commonly held, namely, that they result directly from a protoplasmic differentiation, that they are of nuclear origin, and that they arise from preexisting mitochondria, the author prefers the last mentioned, citing studies more particularly relating to certain algæ and fungi. It is held that each chondriosome arises from one previously existing, but that mitochondria destined for division do not secrete, and those which do secrete do not divide.

The formation of crystalloids of mucorin in mitochondria, F. MOBEAU (Compt. Rend. Soc. Biol. [Paris], 78 (1915), No. 7, vp. 171, 172; abs. in Bot. Centbl., 129 (1915), No. 23, p. 594).—It is stated that in portions of Sporodinia grandis and Rhizopus nigricans mucorin crystalloids are observed to originate and increase in granular mitochondria.

Internal uredinia, J. F. Adams (Mycologia, 8 (1916), No. 3, pp. 181, 182, pl. 1).—Noting instances previously recorded of deviations from normal development, the author reports another aberrant case in the production of internal uredinia by Nigredo caryophyllina (Uromyces caryophyllinus) in the leaves of Dianthus caryophyllus in the greenhouse of the Pennsylvania State College. The deviation here noted from the usual method is thought to represent an abnormal rather than a typical condition.

Asexual hybridization, L. Daniel (Rev. Gén. Bot., 26 (1914), No. 308, pp. 305-341, figs. 8; 27 (1915), Nos. 313, pp. 22-29, figs. 10; 314, pp. 33-49, pls. 3, figs. 6).—After a review of observation and opinion regarding graft hybrids, the author reports on his own more recent observations with four asexual graft hybrids. These have been studied somewhat in detail as regards their characters, both external and internal, at different stages. It is considered as of theoretical and practical importance that occasionally this form of hybridization gives rise to characters not previously possessed by either of the stocks concerned in its formation.

Variation in Cosmos bipinnatus, B. Longo (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), II, No. 9, pp. 408-410).—A descriptive account is given of the variation observed for two consecutive years in the generations of C. bipinnatus.

Seashore thicket formation by Prunus spinosa, H. Devaux (Rev. Gén. Bot., 27 (1915), No. 320, pp. 225-235, pl. 1, figs. 2).—A description is given of some

striking effects as regards position and contour produced by wind action in connection with growth and death in thickets of *P. spinosa* in exposed situations on the seashore.

Differences in resistance of plants to injurious influences, F. Stranák (Věstnik 5. Sjez. Čes. Lék. Přír., 1915, p. 425; abs. in Bot. Centbl., 129 (1915), No. 15, p. 378).—Important phases of the resistance of plants to attack are their anatomical structure (as mechanical tissue or impregnation with silica), morphological characters (as thickness of stems in cereals), chemical constituents of the plant body (as silica or lime), and vegetative period.

The effects of illuminating gas on plants, P. SORAUER (Landw. Jahrb., 48 (1915), No. 2, pp. 279-312, pl. 1, figs. 2).—Previous investigations (E. S. R., 26. p. 532) have been followed up with a study of the various effects of illuminating gas in the soil on several sorts of wild or cultivated plants, largely trees. The results are detailed as regards the influences noted, including reactions by the plants. It is thought that, while a number of indications are found which, taken together, may be considered as characteristic of root injury by gas, no single symptom, as for example changes in leaf coloration, can be depended upon as a certain indication of gas injury to roots.

The influence of sulphur dioxid on plants, R. TRNKA (Věstnik 5. Sjez. Čes. Lék. Přír., 1915, p. 431; abs. in Bot. Centbl., 129 (1915), No. 15, p. 378).—Plants are said to take up into their active green tissue sulphur dioxid in different proportions. This is thought to form sulphurous or sulphuric acid and to interfere greatly with the formation of vegetable matter.

Secretion by roots of substances toxic to plants, M. Molliard (Rev. Gén. Bot., 27 (1915), No. 322, pp. 289-296, pl. 1).—Work previously reported (E. S. R., 30, p. 522) has been followed up by further tests with peas. These are said to show that the plants excrete substances which prove toxic to plants grown thereafter in the medium previously used. The effect was increased after the medium had been twice used.

Injurious effects from ivy growing on trees, C. von Tubeuf (*Naturus*. *Ztschr. Forst. u. Landw.*, 13 (1915), *No.* 10, pp. 476-481, figs. 5).—This is a further account, with discussion, of stem constrictions of plants (E. S. R., 31, p. 343).

### FIELD CROPS.

Field crops, D. N. PRIANISHNIKOFF (Uastnoe Zemledielie. Moscow: V. Rikhter, 1914, pp. 513+15, pls. 144, figs. 2).—This work deals with cereal, root, and leguminous crops. together with other plants grown for oil, fiber, dye, and spice production. Attention is also given to tobacco and other plants used for their narcotic effect. The culture and uses of the different crops are considered in detail and the control of diseases and insect enemies is outlined. The work has reference to the culture of the different crops in Russia.

[Irrigation experiments at Bromberg] (Jahresber. Kaiser Wilhelms Inst. Landw. Bromberg, 1914, pp. 38-50).—Potatoes were given 30, 140, and 160 mm. (1.2, 5.6, and 6.4 in.) of irrigation water, applied by sprinkling, in addition to a rainfall of 195 mm. during the growing season. A forage variety, Gertrude, yielded 13,209 lbs. of tubers per acre without irrigation and 15,262 lbs., 15,440 lbs., and 19,099 lbs. per acre when receiving 30, 140, and 160 mm. of irrigation water, respectively. Magnum Bonum, a table variety, yielded 4,462 lbs. with only the natural rainfall and 10,710 lbs. and 10,978 lbs. per acre with 140 and 160 mm. of irrigation water, respectively. On the assumption that both rain and irrigation water was completely used by the plants, it is pointed out that it required on the average of all tests 556 lbs. of water to produce 1 lb.

of dry substance in the tuber. In another experiment, conducted on a heavier soil, it was found that irrigation did not increase the yield of tubers to the same extent as in the experiments just described, which were conducted on sandy soil, and the starch content also was increased to only a very limited extent. The percentage of large-sized tubers in the crop, however, appeared to have been increased considerably as the result of irrigation.

In addition to these trials an experiment was conducted with the use of different quantities of waste water from potash works applied with the irrigation water. Although as high as 1.2 kg, of chlorin were given per cubic meter of water applied, no injurious effects on the growth and yield of the potatoes was observed, but the foliage was considerably lighter in color than the foliage of the plants irrigated with pure water and the crop ripened about three weeks earlier.

Sugar beets received a natural precipitation of 237 mm, from May 1 to September 30, and were given in addition on certain plats either 130 or 220 mm, of irrigation water. The plat irrigated with 130 mm, produced 8,300 lbs. of beets and 3,213 lbs. of leaves more per acre than the plat not irrigated. The use of 220 mm, of water apparently reduced the yield of beets and leaves as compared with the application of 130 mm. The results indicated that it required an average of 334 lbs. of water to produce 1 lb, of dry matter in the beets and foliage.

Irrigation of meadows on light sandy soil by the furrowing, flooding, and furrow-gravity methods gave very satisfactory results, the best yield being secured with furrow-gravity irrigation.

Ten years of variety tests at Dickopshof, A. RICHARDSEN (Landw. Jahrb., 48 (1915), No. 3, pp. 331-427).—The soil conditions of the experiment field are described, data with reference to the weather conditions for the different years are tabulated, the crop rotations followed are outlined, and the methods of conducting the variety tests with winter and spring wheats, winter rye, oats, barley, sugar beets, fodder beets, ruta-bagas, and potatoes are discussed. The soil devoted to these tests is described as a deep loam with favorable physical characters, although not especially satisfactory from a chemical point of view. The meteorological observations showed a ten-year average of 9.6° C. (49.1° F.) as the mean daily temperature for the year, an annual sunshine total of 1,107 hours, and an annual precipitation of 695 mm. (27.8 in.). The results are tabulated in detail for the different years and are summarized for different periods.

Of three winter wheat varieties grown for seven years, Strube Club gave an average yield of 3,321 kg. of grain and 5,399 kg. of straw per hectare (49.4 bu. and 5,339 lbs. per acre, respectively). Mette Club yielded on the average 3,161 kg. of grain and 5,830 kg. of straw per hectare. Strube Club also stood first among the varieties grown for periods of six, five, and four years, but ranked second—Mette Club standing first—among 11 varieties tested from 1911 to 1913, inclusive. In a seven-year test the grain produced by the two varieties represented an average of 35.4 per cent of the total yield, while the average liter weight was 760.3 gm., and the average weight of 1,000 kernels 37.709 gm.

From the results secured with spring wheat it is concluded that for the soil conditions of the test, Heine Japhet and Rimpau Red Schlanstedt are of equal value and apparently superior to the other varieties tested, while Krafft Bordeaux, Wohltmann Blue Dame, and Iden are considered promising sorts approaching each other in yielding capacity. In one seven-year test Rimpau Red Schlanstedt, the leading variety, yielded on an average 2,927 kg. of grain and 5,815 kg. of straw per hectare. As compared with the winter wheat varieties, the spring wheat varieties gave a higher average weight per liter

and per 1,000 kernels, but the average percentage of grain as based on the total yield of grain and straw was higher with the winter wheat varieties.

The test of varieties of winter rye showed Lochow Petkus as the leading sort, with Himmel Champagne ranking next, and Sperling Green Kerneled, Krafft Zeeland, and Rümker Yellow Kerneled as promising varieties. In a nine-year test Lochow Petkus produced on an average 2,775 kg. of grain and 5,996 kg. of straw per hectare, while Himmel Champagne yielded 2,630 kg. of grain and 5,674 kg. of straw, but ranked above the other variety in average percentage of grain, liter weight, and 1,000-kernel weight.

The leading variety of oats in tests carried on for six, five, and four years was Strube Schlanstedt, followed by Svalöf Goldregen and Leutewitz Yellow. In the three and two year tests all these varieties fell below Lochow Yellow and Svalöf Siegeshafer. In the six-year test the varieties above mentioned yielded an average of 3,423 kg. of grain and 4,718 kg. of straw per hectare, the proportion of grain to total production being 42.05 per cent, the liter weight 513 gm., the 1,000-kernel weight 28.081 gm., and the proportion of hull in the grain 25.09 per cent.

Varieties of brewing barley were tested for only three years. The average grain production was in favor of Improved Pfalz, yielding 3,821 kg. of grain and 4,804 kg. of straw per hectare. This variety also ranked first in proportion of grain to total yield with 44.45 per cent, in liter weight with 690.5 gm., and in 1,000-kernel weight with 48.39 gm. The average protein content was 11.85 per cent which, although rather high, was nevertheless lower than in any other variety. Nolc Bohemia and Heil Frankengerste stood next in value.

The data secured with varieties of sugar beets indicated in general that a decrease in beet production was associated with an increase in leaf production, not only relatively but also absolutely and as a rule with an increasing percentage of sugar. As a result of this relationship it is pointed out that the sugar production per hectare fluctuates much less than the beet production and the percentage of sugar content. In beet yield the variety Friedrichswerth, among four varieties tested for eight years, ranked first with 42,392 kg. of beets and 29,882 kg. of leaves per hectare. The average sugar content of the beet, 16,22 per cent, was lower than in the other varieties but the average sugar production per hectare, 6,876 kg., was the highest This was also generally true of the results secured in the tests of shorter duration and with a larger number of varieties. For sugar production the varieties Breustedt, Schobbert Specialty 1, and Schobbert Ideal 1 ranked next to Friedrichswerth.

The results with varieties of fodder beets showed that a decrease in beet yield was accompanied by an increase in leaf production, not only in the percentage relation of the leaves to the beet, but also in the production per hectare, and also in general by an increase in dry matter content. It is pointed out that for this reason the dry matter yield per hectare varies less than the beet yield and the percentage dry matter content. Of four varieties tested for nine years, the leading variety, Yellow Eckendorf, yielded an average of 85,913 kg. of beets and 10,966 kg. of leaves per hectare. The average dry matter content of the beet was 11.17 per cent. While this variety was the heaviest yielder of beets, it fell behind the other sorts in dry matter content and dry matter production, the average for the four varieties being 13.52 per cent and 10,314 kg. per hectare respectively. Two varieties, Durana and Veni Vidi Vici, stood well above the average in dry matter production per hectare.

The test with rutabagas was conducted for only three years and limited to only three varieties. The leading variety, Remy Improved Altmark Giant, yielded 65,000 kg. of beets per hectare with a dry matter content of 12.57 per cent.

Study of the root systems of pasture plants on the moor soils of the experiment fields at Flahult and Torestorp, H. Osvald (Mitt. Ver. Förd. Moorkultur Deut. Reiche, 34 (1916), No. 4, pp. 62-76, figs. 10).—Observations made on the depth and distribution of the root systems of white clover, timothy, meadow foxtail, Kentucky bluegrass, meadow fescue, red fescue, and orchard grass growing on lowland and upland moor soils were supplemented by studies of the root anatomy.

On the upland moor meadows at Flahult a dense and heavy root growth occurred in the upper 5 cm. (2 in.), in the next 25 cm. the growth was very thin, while below 30 cm. practically no roots were found. The lowland moor meadows of Torestorp showed a dense and heavy root development in the upper 15 to 20 cm. which gradually became thinner as it extended to the depth of 45 cm.

The results of the anatomical studies indicated that roots from moor soils are less densely constructed, have larger intercellular spaces, and lignify more slowly than roots produced in sandy soil. The larger intercellular spaces which always occur in such grasses as meadow foxtail, and meadow fescue, and timothy are produced much earlier on moor soils and often are found even in very young roots. This is considered due to the inadequate supply of oxygen in the soil and this behavior of the plant as an effort on its part to provide aeration. The absence of root nodules on clover is regarded as further evidence of the lack of oxygen in the soil. On the upland moor soils at Flahult, nodules are found only in the upper 2 or 3 centimeters. The results are taken as showing plainly that on moor soils only a very thin surface layer serves as the source of moisture and nutrients to meadow plants.

Several methods of laying down cultivated land to meadow, S. Rhodin (K. Landtbr. Akad. Handl. och. Tidskr., 54 (1915), No. 7, pp. 569-582; Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 115 (1915), pp. 16).—Three different methods of seeding cultivated land to timothy and clover were compared. The seed mixture used consisted of 3 kg. of red clover, 6 kg. of alsike clover, and 21 kg. of timothy per hectare (2.67, 5.34, and 18.69 lbs. per acre). In all cases oats was used as a nurse crop. In one instance the clover and timothy seed was mixed with the oats and the whole sown on smoothly harrowed soil at the rate of 175 kg. per hectare; in another instance the seed mixture was sown on smoothly harrowed land before the nurse crop; and in the third on unharrowed land and after the nurse crop, the land being then smoothed down with the harrow.

The best results were obtained from sowing the seed mixture before the nurse crop. It was also found that covering the clover and grass seed not more than 1.5 cm. (about 0.6 in.) proved most satisfactory.

Corn culture in the Southeastern States, C. H. KYLE (U. S. Dept. Agr., Farmers' Bul. 729 (1916), pp. 19, figs. 11).—This publication makes recommendations and suggestions regarding the preparation of land for corn, the use of commercial fertilizers in corn culture, and the planting and cultivation of the crop, applicable mostly to the cotton-growing sections of North Carolina, South Carolina, Georgia, Florida, and Alabama.

Cotton, H. Semler (O Algodão. Rio de Janeiro: Min. Agr., Indus. e Com., 1914, pp. 110, figs. 40).—This is a popular treatise on the cotton industry, including a botanical and historical review of the plant, directions for its culture, a description of ginning and other processes of preparing the crop for the market, and statistical notes on the production of cotton for different years and countries.

Observations on the blossoming of hemp, G. Havas (*Kisérlet. Közlem., 18* (1915), No. 5-6, pp. 908-919, pls. 2, figs. 3).—Hemp plants were grown in the open in 1913 and observations were made every fourth hour from 4 a.m. until 8 p. m. during the blossoming period.

It was observed that in both the staminate and pistillate plants blossoming began at one of the upper nodes on the stem and progressed gradually upward. In vigorous plants with branches from the lower nodes, the progress of blossoming was both upward and downward from the initial blossom, while on the branches themselves the opening of the buds proceeded toward the point. The blossoming of the male plants progressed in such a way that the buds at the ends of the main stem and branches all opened at the same time. The male flowers were found to develop on the leafless portions of the floral axis and the female flowers grouped in pairs in the axils of the leaves. Lateappearing and subordinate branches as a rule bore no flowers. It was further observed that under identical conditions female flowers sometimes reached the receptive stage before the male flowers were ready to supply the pollen. It is stated that in Hungary pollen distribution generally begins during the first half of July, continuing from four to six weeks; that plants may be in blossom from three to four weeks, and that several thousand blossoms may develop on a single plant. The dehiscence in the staminate flowers took place to the greatest extent during the night and early morning. The development of individual buds from blossoming to pollination required about seven hours.

Sorghum vulgare and S. halepense, G. C. Dudgeon (Min. Agr. Egypt, Agr. Prod. No. 1a (1915), pp. 32).—A general article in encyclopedic form, dealing with S. vulgare, under the principal headings of its botanical description, history, cultivation, value of the crop, uses of the grain, leaves, and stalks, areas and yields, prices and returns, food value, sweet sorghum, and broom sorghum. With regard to S. halepense only brief notes on botanical relationship and its culture are presented.

Sudan grass, N. Schmitz (Maryland Sta. Bul. 194 (1916), pp. 47-62, figs. 7).—A general discussion of Sudan grass culture in Maryland is presented and the results of cultural and other tests with the crop are reported.

In 1913 better yields on soils of high and medium fertility, 4.4 and 3.3 tons per acre, respectively, were secured from sowing on June 13 than on earlier and later dates. The average results for three years indicated that under favorable soil conditions 15 lbs. of good seed is sufficient for securing a satisfactory stand. Sudan grass and soy beans as a mixed crop gave the best yield when the Sudan grass was sown at the rate of 15 lbs. and the soy beans at the rate of 6 pks. per acre. The composition of Sudan grass hay, cleaned seed, and straw is given in a table and compared with the composition of other common forage crops. In a digestion test with a bull, coefficients were obtained of 60.6 per cent for dry matter, 35.4 for protein, 41.2 for fat, 50 for crude fiber, and 62 per cent for nitrogen-free extract.

Studies of variation and correlation of weight and sugar content of beets, especially of sugar beets, W. Ötken (Ztschr. Pflanzenzücht., 3 (1915), No. 3, pp. 265-333, figs. 2).—This article deals mainly with the study of correlation between individuals and between the averages of groups of plants. The results obtained are tabulated in detail and discussed at some length.

The conclusions based on the data accumulated are drawn with reference to the present status of sugar-beet breeding. Belief is expressed in the existence of a series of factors influencing the increase in sugar content either directly or indirectly, and in the combination of an increasing number of these factors through the continued selection of beets high in sugar or the selection and reciprocal crossing of families readily transmitting their characters. The breed-

ing of families in which external conditions least affected the sugar content unfavorably is considered to have resulted in the final exclusion of a series of factors which under certain conditions cause a reduction of the sugar content, and this, in conjunction with the gradual fixation of the characters positively determining a higher percentage of sugar, has reduced in the course of time the variability of the sugar content of the beet. The author states that it has been shown repeatedly that the sugar content increases with the intensity of culture, and that for this reason the richest beets are still produced in the long and well established beet-growing centers. He further states that possibilities present themselves to increase the yield of beets as well as the percentage of sugar without detriment to either the one or the other character.

Further conclusions based on the data in hand, but with reference only to heritability, are drawn and presented by T. Roemer, who points out that external conditions have a marked influence on the growth of sugar beets in general, but that the weight of the beet as compared with its sugar content is affected to a greater extent and that its latitude of variation is also the greater. For this reason the increase in weight is regarded as more difficult of achievement than the increase in sugar content, as selection based on weight is more likely to include a higher percentage of nontransmissible characters than selection based on sugar content, and the distinction between heritable and nonheritable variations presents greater difficulties. Attention is called to the fact that the transmission of desirable characters is not the same in either individual plants or in entire families, and that in selection for weight and sugar content a certain influence of the mother beet asserts itself. This is largely determined by the family type, so that the performance of the family is of much greater importance in selection than the performance of the individual. It is stated that weight and sugar content as heritable characters act independent of each other, as inheritance of greater weight and higher sugar content may be coincident with each other or undesirable inheritance of one character may be coupled with desirable inheritance of the other.

The relation between the sugar content and chemical characters in the first generation of an individual mother beet, K. Andrlík and J. Urban (Ztschr. Zuckerindus. Böhmen, 40 (1915), No 3, pp. 107-113).—The results of a study of this question indicated that individual beets of the first generation with the same sugar content may vary within the limits of variation in the weight of the root and leaves. The law of correlations appeared operative to only a very small degree with regard to the average sugar content of the roots and their average weight, but seemed of greater significance in connection with the weight of the leaves, as a higher average sugar content was associated with a lower average weight of leaves. It was found that with the same sugar content in the root, the dry matter in the root and leaves varied within the limits recognized for this factor, but that an average low sugar content was generally accompanied by an average low dry matter content in the root and leaves. The ash content of the root and leaves varied in roots of the same sugar content, but in general rose perceptibly in the leaves with a high average sugar content in the root, and vice versa. The data also indicated that with the increase in the average sugar content of the root, the nitrogen content of the root and leaves increases although only to a limited degree.

Tobacco, H. Semler (O. Fumo. Rio de Janeiro: Min. Agr., Indus. e Com., 1914, pp. 131, figs. 19).—A popular treatise on tobacco including discussions from the historical, botanical, and cultural standpoints. Notes by A. Caire on the development of tobacco culture, the total yields in different countries, and the quantities exported by Brazil in different years are appended.

Tobacco from Cyprus (Bul. Imp. Inst. [So. Kensington], 13 (1915), No. 4, pp. 547-550).—An article describing a number of samples of Turkish tobacco grown in Cyprus, and giving in this connection the chemical composition of two of the samples.

It is pointed out that some of the samples conform with Turkish tobacco as regards size of leaf but that they contain too much moisture for the English market. It is stated that the excess of moisture caused a rapid secondary fermentioned in the tobacco resulting in dark patches around the midrib.

Frost and wheat, A. H. COCKAYNE (Jour. Agr. [New Zeal.], 12 (1916), No. 1, pp. 1-10, figs. 7).—This article discusses the fertilization of wheat in its relation to frost injury and reports observations made on the effects of a late frost in New Zealand.

In nearly every case the wheat crops which failed to become fertilized as the result of frost injury were autumn sown. It is pointed out that this was not because of the time of sowing but because the crops happened to be in a critical stage when the frost injury occurred. The wheat crops fully fertilized at the time of the frost and whose flowers had closed again were not damaged at all, while spring sown wheat not yet developed to the stage of fertilization was injured more or less where the frost was most severe. These spring sown crops did not show the complete lack of fertilization seen in those that were on the point of flowering when the frost occurred.

Second annual seed laboratory report, 1914–15, W. L. Oswald (Minnesota Sta. Bul. 159 (1916), pp. 3–16, figs. 4).—During the year 8,452 samples were sent in for examination and 125 official samples were collected. The results of purity and germination tests are given in tables.

The use of a sunlight germinator in testing grass and flower seeds gave promising results. It was found that many of the grass seeds germinate best in the light. An experiment in testing the germination of seeds in soil and sand in the greenhouse as compared with the chamber tests in the laboratory showed that in nearly every case the laboratory test gave a somewhat higher percentage of germination than was secured in the soil test in the greenhouse.

Weeds and their identification, E. Atkinson (Jour. Agr. [New Zeal.], 12 (1916), No. 1, pp. 32-39, figs. 9).—Descriptive notes are given on capeweed (Cryptostemma calendulaceum), hawkyeed (Crepis capillaris), and hawkbit (Leontodon hirtus), as they occur under New Zealand conditions.

### HORTICULTURE.

Plant propagation, M. G. Kains (New York: Orange Judd Co., 1916, pp. XIX+322, figs. 214).—In the present manual and textbook the author has aimed to bring together the latest information on all branches of practical and theoretical plant propagation with the view of making the work valuable both to the professional propagator and to the teacher of plant propagation.

The successive chapters deal with the following subjects: Germination; germination and longevity of seeds; seed testing; potting; propagation by buds—layerage; bottom heat; cuttage; classes of cuttings; graftage—gen ral considerations; is graftage devitalizing; Daniel's experiments and conclusions; general points concerning fruit tree stocks; stock and scion handling; grafting waxes, wound dressings, etc.; methods of grafting; methods of budding; nursery management; laws affecting nursery stock; and suggested practicums.

Plant propagation in the Tropics, P. J. Wester (Philippine Bur. Agr. Bul. \$2 (1916) pp. 87, pls. 12, figs. 40).—In this bulletin the author first discusses the principles and methods of plant propagation with special reference to their application in the Tropics. Directions are then given for the vegetative propa-

gation of tropical and semitropical fruits, tree planting, orchard management, and the control of the more common diseases and insect pests. A list is given of tropical fruits in the Philippines.

[Ornamental and economic plants in the Botanic Gardens], C. K. Bancroft (Rpt. Dept. Sci. and Agr. Brit. Guiana, 1914-15, App. 2, pp. 3-12).—Notes are given on ornamental and economic plants of various kinds being grown in the Botanic Gardens, Georgetown, British Guiana.

Annual report of the experimental work of the Ganeshkhind Botanical Garden (Poona District) for the year 1914-15, W. Burns (Dept. Agr. Bombay, Ann. Rpt. Expt. Work Ganeshkhind Bot. Sta. 1914-15, pp. 47).—A progress report on cultural experiments, variety tests, and miscellaneous experiments being conducted with fruits and other economic plants in the Ganeshkhind Botanical Garden.

In a college garden, VISCOUNTESS WOLSELEY (London: John Murray, 1916, pp. XVII+255, pls. 8).—A popular account of the development and work of the Market Garden School, for women, at Glynde, Sussex.

A second report on the university farm garden, A. L. Dacy (West Virginia Sta. Bul. 156 (1916), pp. 3-22, figs. 5).—In continuation of a previous report (E. S. R., 33, p. 237) the results secured at the university farm garden for the third season are given, together with an average of the results obtained during the three years 1913 to 1915. The average gross annual receipts for the 3-year period from 4.7 acres were \$275.48 per acre. Among the crops grown three years were celery with an average annual receipt of \$533.22; eggplant, yielding \$462.73; and tomatoes, early and late, yielding \$405.66 per acre. Cauliflower, which was grown but two years, gave an annual gross receipt of \$433.24 per acre.

A master farmer of seventy who grows truck crops and fruit in southern Jersey, H. R. Cox (Country Gent., 81 (1916), No. 26, pp. 1251, 1252, figs. 5).—In addition to a brief account of operations on a successful fruit and truck farm a table is given containing an analysis of the business of the farm for the fiscal year ended March 1, 1916. One hundred and thirty-three acres of crops grown in that year yielded a labor income of \$3,583.

Onions.—Experiments and culture, T. H. White (Maryland Sta. Bul. 195 (1916), pp. 63-78, figs. 3).—This bulletin gives the results of a number of miscellaneous experiments with onions conducted over a period of several years, together with directions for onion culture in Maryland.

In variety tests Gigantic Gibraltar grew the largest and made the best yield. Prizetaker, White Victoria, and White Globe all yielded well. Hotbed grown plants on the average produced more bushels per acre than either sets or seeds sown outside. Poultry manure at the rate of 5,000 lbs. per acre, supplemented with 98 lbs. of sulphate of potash per acre, gave an increased yield of 36 bu. of onions over the check. A fertilizer containing 2 per cent potash obtained from muriate produced a better yield than a fertilizer containing either 4 or 8 per cent potash. Rows of onions planted 30 in. apart for horse cultivation yielded only 85.7 bu. per acre as compared with 130.6 bu. for rows 14 in. apart and cultivated by hand.

Composition of tomatoes from blighted vines, W. D. BIGELOW (Canner, 43 (1916), No. 1, p. 30).—The author finds that analyses of half-grown fruit which has ripened on a blighted vine are practically identical with those of half-grown tomatoes picked from a healthy vine. Although not any more injurious to health than a green tomato, prematurely ripened tomatoes are considered to be undesirable for use as canning stock on account of the inferiority of the product made from them.

Bordeaux mixture stains removed, M. G. Kains (Country Gent., 81 (1916), No. 23, p. 1161).—Experiments reported by the author indicate that tomatoes and other vegetables stained with Bordeaux mixture may be freed from stain by dipping the vegetables in a solution of acetic acid. In the work here noted, which was conducted with tomatoes, a solution of half a cupful of pure acetic acid to 2 gal. of water was used. The dipped tomatoes were readily cleansed of the newly-formed acetates by passing the fruit under running water.

Report of general fruit committee, J. P. Stewart (*Proc. State Hort. Assoc. Penn.*, 57 (1916), pp. 15-20).—In this paper the author briefly reviews some of the more important work of the department of experimental pomology of the Pennsylvania Experiment Station.

The time of blossoming of fruit trees (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1914, pp. 107-116).—Records for 1914 are given of the flowering dates of individual varieties of fruit trees grown in the plantations and orchards of the National Fruit and Cider Institute, Bristol.

The history of the classification of apples, E. A. Bunyab (Jour. Roy. Hort. Soc., 41 (1916), No. 3, pp. 445-464, pls. 4).—In this paper the author discusses the many attempts that have been made in the past to devise a system of classification for apples. The subject matter is presented for the special purpose of showing wherein such classifications have proved unsatisfactory.

Cultural methods in bearing orchards, J. P. Stewart (*Pennsylvania Sta. Bul. 141 (1916*), pp. 3-28, figs. 5).—In a previous bulletin of the station the results of some of the author's cultural experiments in young apple orchards were reviewed (E. S. R., 33, p. 238). The present bulletin gives the results through the season of 1915 of six experiments started in bearing orchards in 1907-8. The experiments involved a comparative test of mulch, sod, tillage, and cover crop treatments, both with and without fertilizers.

Summing up the results thus far obtained it is found that the mulch treatment reinforced by outside materials has been most efficient in improving the yield, growth, and average size of the fruit in orchards up to about 20 years of age. It has also been most efficient in conserving moisture in all cases that have been determined. For orchards over 20 years of age tillage and cover crops slightly surpassed the mulch treatment, unless it was accompanied by adequate fertilization.

The sod treatment has usually given the lowest results in yield, growth, and average size of fruit in orchards of all ages, except when aided by special conditions. On the other hand, it has excelled in color of fruit and in freedom from blight. Fertilized sod plats have generally given better results than unfertilized plats receiving a mulch or tillage. Both the sod and the mulch treatments require thorough protection against mice.

Tillage has generally done best in the fully matured orchards, where it is especially efficient in stimulating growth. Tillage has done well in the younger orchards when accompanied by proper fertilization. The experiments with tillage as a whole indicate that plowing deeper than 4 in. is probably undesirable and that most of the cultivation should be done with disk harrows, or similar shallow-working cultivators rather than the plow. Cover crops have not proved especially beneficial unless the moisture supply was unusually good or the amount of food added was extra large.

In most of the experiments there has been a very close correlation between growth and bearing, except in the older orchards, when it is often possible to secure more growth than is necessary to maintain the best yields. Two of the experiments indicate that annual crops may be maintained by such biennial bearers as Baldwin and Spy in the presence of ample food and moisture supply, by regulation of the yield in any year to prevent overbearing and by preventing

injury to the root systems. In some cases there has been a very marked correlation between the amount of fire blight and the rate of growth. The greatest damage has occurred uniformly on the trees making the most growth. In view of the fact that weakly growing trees have also been attacked, it appears that it is the intermediate growth that is most resistant to this disease.

With regard to color in apples the author concludes that the red colors in apples are developed primarily by sunlight in the later stages of maturity. Hence conditions favoring either of these factors, such as late picking, open pruning, long growing season, sparse foliage, fully developed fruit, light soils, or sod culture, will increase this color, while all opposing conditions will decrease it. By a proper utilization of one or more of these conditions it is believed that the customary harmful effects on color of heavy tillage or too much nitrogenous fertilizer may generally be overcome.

The size of the fruit is determined chiefly by the moisture supply, hence the cultural methods that conserve moisture most efficiently will normally produce the largest fruit. Other influences of importance are the number of fruits on the tree, supply of plant food, and the temperature and length of the growing season.

Starch in apple trees, W. A. PRICE (Ohio Jour. Sci., 16 (1916), No. 8, pp. 356-359).—An experimental study of the storage and migration of starch in apple trees is reported.

The author finds in substance that "during the dormant period starch reserve is stored in the living cells of the pith, wood parenchyma, and medullary rays of the apple. With approach of spring, starch is found in the tissues of the bark, appearing first in the phelloderm and collenchyma. As the leaves begin to appear starch begins to disappear from the various tissues in order as follows: Bark, wood parenchyma, rays, pith. It is used first from the youngest wood of the branches in the top of the tree, later from the lower portions of the tree, and finally from the roots. A portion of the starch reserve may never be used in the growth of the tree, but remains behind to be included in the heartwood, where it remains indefinitely and renders the wood susceptible to decay."

Stock influence upon vintage quality and other characters of apples, B. T. P. BARKER (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1914, pp. 117-127).—The results are given of analyses made in 1914 of fruit juices from apples growing on different stocks. The data secured confirm the conclusion previously arrived at as to the negligible effect of the intermediate stock on vintage quality (E. S. R., 33, p. 240).

Crown gall and resistant stocks, C. O. SMITH (Cal. Citrogr., 1 (1916), No. 9, p. 14, fig. 1).—Studies are being conducted at the California Citrus Experiment Station with the view of securing resistant stocks for stone fruits.

Tabular results are here given showing the representative resistant and susceptible species and varieties in the various classes of stone fruits which were subjected to the crown gall by actually inoculating the rapid-growing twigs and branches with pure cultures. Among the almonds inoculated no marked resistance has been found. Stocks of the Domestica and Damson types of plums and certain Asiatic types of apricots showed the strongest resistance. The Golden Beauty variety of *Prunus hortulana* has shown sufficient resistance to be used as a stock for native plums. Among other American species, *P. pumila*, a dwarf stock used to some extent in the Middle West, was also strongly resistant.

The Japanese mountain cherries, wild forms and cultivated races, M. Miyoshi (Jour. Col. Sci. Imp. Univ. Tokyo, 34 (1916), Art. 1, pp. 175, pls. 23).—A systematic study of the wild and cultivated forms of Japanese mountain cherries, including descriptions of species and varieties. The descriptive text

is accompanied by a number of illustrations in color of the floral parts and foliage of various forms of cherries, as well as illustrations showing the tree growth.

Peach package tests, season of 1915, J. M. CREELMAN (Agr. Gaz. Canada, 3 (1916), No. 3, pp. 222-225, figs. 3).—Data are given on shipping tests of various types of peach packages conducted under the direction of the Canadian Department of Agriculture in 1915.

The new vine; the hybrid producers, E. Pée-Laby (La Vigne Nouvelle; Les Hybrides Producteurs. Paris: J. B. Baillière & Sons, 1915, pp. 72).—An account of the direct bearing hybrid grapes resulting from crosses between American and French species. The introductory chapter describes the principal characters of hybrid producers. The succeeding chapters deal with the cultural value of different color hybrids as well as their resistance to diseases, and the nature of the wines made from them.

The chemical composition of the Chasselas Doré and the advantages of bagging in keeping the grapes fresh, F. Charmeux (Jour. Soc. Nat. Hort. France, 4. ser., 17 (1916), May, pp. 72-74; June, pp. 90-93).—In some experiments in bagging grapes here reported it was found that the use of close paper bags not only prolongs the fresh appearance of the bunches but also gives the berries a more uniform quality and development and somewhat increases the sugar content of the grapes.

Official report of the session of the International Congress of Viticulture, San Francisco, Cal., July 12, 13, 1915 (Off. Rpt. Sess. Internat. Cong. Vit., 1915, pp. 324, figs. 54).—These proceedings include the following papers, with discussions, delivered at the Congress: The Work of the State Viticultural Commission, by E. M. Sheehan (pp. 19-22); Probable Effect of the Federal Tax on Brandy upon the Horticultural Interests of California, by R. D. Stephens (pp. 23, 24); A Campaign of Wine Education, by H. F. Stoll (pp. 24-29); Early California Wine Industry, by H. Lachman (pp. 29-32); Love of the Vine, by L. J. Vance (pp. 32-35); Grape Breeding, by R. D. Anthony (pp. 35-39); Introduction of Viticulture into the Schools, by A. W. Miller (pp. 39-43); Resistant Vines, by G. C. Husmann (pp. 45-50); Pruning and Training American Grapes, by F. E. Gladwin (pp. 50-62); Commercial Fertilizers for American Grapes, by F. E. Gladwin (pp. 62-68); Phylloxera-Resistant Stocks in California, by F. C. H. Flossfeder (pp. 69-76); Vitis vinifera in Eastern America, by U. P. Hedrick (pp. 77-81); Viticulture on the Pacific Coast, by F. T. Bioletti (pp. 81-88); The Vineyards of the Columbia River Basin, by E. H. Twight (pp. 89-91); The Grape in Oregon, by C. I. Lewis (pp. 91-97); Grape Growing in New Mexico, by F. Garcia (pp. 97-102); Grape Growing in Utah, by A. B. Ballantyne (pp. 102-106); Grape Growing in Imperial Valley, by W. E. Packard (pp. 107-110); Grape Anthracnose in America, by C. L. Shear (pp. 111-117); Powdery Mildew of Grapes and Its Control in the United States, by D. Reddick and F. E. Gladwin (pp. 117-125); Studies on Plasmopara viticola (Downy Mildew of Grapes), by C. T. Gregory (pp. 126-150); Methods of Preparation and Relative Value of Bordeaux Mixtures, by O. Butler (pp. 151-160); Sulphur Fungicides, by G. P. Gray (pp. 160-174); Grape Insects in California, by H. J. Quayle (pp. 174-181); Phylloxera in California, by R. L. Nougaret (pp. 181-186); The Grape Root Worm (pp. 187-195), The Grape Leafhopper (pp. 195-201), the Grapevine Fleabeetle (Haltica chalybea) (pp. 201-209), and The Rose Chafer (Macrodactylus subspinosus) (pp. 210-216), by F. Z. Hartzell; the Grape Berry Moth (Polychrosis viteana), by W. H. Goodwin (pp. 217-236); Two Destructive Grape Insects of the Appalachian Region, by F. E. Brooks (pp. 237-248); The Engineer's Part in the Advancement of the Viticultural Industry, by E. T. Meakin (pp. 248-253); Some Results of the Practical

Application of Sulphurous Acid and Selected Yeast in the Fermentation of California Wines, 1913 and 1914, by W. V. Cruess (pp. 254–263); A Simple and Rapid Method for the Estimation of Volatile Acid in Wine, by W. V. Cruess and R. W. Bettoli (pp. 263–267); Influence of Composition on Effervescence of Champagne, Preliminary Investigations, by R. W. Bettoli and J. La Belle (pp. 267–275); The Sugar and Acid Content of American Native Grapes (pp. 276–279), and The Composition of Pure Wine from American Native Grapes (pp. 280–287), by W. B. Alwood; Important Factors Governing the Successful Transportation of Table Grapes, by A. V. Stubenrauch (pp. 288–300); The Intelligent Blending of Wines, by H. S. Dewey (pp. 301, 302); A New Utilization of a By-Product of the Grape, by G. Rossati (pp. 303–307); and Relation of the Maturity of the Grapes to the Quantity and Quality of the Raisins, by F. T. Bioletti (pp. 307–315).

The wild blueberry tamed, F. V. COVILLE (Nat. Geogr. Mag., 29 (1916), No. 6, pp. 535-546, figs. 10).—In this article the author briefly reviews the progress that has been made in his cultural and breeding experiments with blueberries (E. S. R., 34, p. 534), and also in the culture of improved forms on the New Jersey trial plantation. On this plantation hybrid seedlings have borne their first commercial crop when only three years old and a crop three times as large when four years old.

Official proceedings of the twelfth annual convention, Michigan State Association of Ginseng Growers, 1916 (Off. Proc. Ann. Conv. Mich. State Assoc. Ginseng Growers, 12 (1916), pp. 45).—Various topics dealing with the culture and subsequent preparation of ginseng and goldenseal as discussed at the convention are included in these proceedings.

A preliminary study of Philippine bananas, N. G. Teodoro (*Philippine Jour. Sci.*, Sect. C, 10 (1915), No. 6, pp. 379-421, pls. 12).—A descriptive account of the species and varieties of bananas known to occur in the Philippines, in which special attention has been given to the special purposes to which the different varieties are adapted.

[Cacao in British Guiana], J. B. Harrison (*Rpt. Dept. Sci. and Agr. Brit. Guiana*, 1914-15, pp. 26-30).—The results of manurial and other cultural experiments with cacao in British Guiana are reported.

The experiments, which were commenced in 1900, indicate that in British Guiana under conditions similar to those existing at Onderneeming farm the methods of cultivation leading to the successful growth of cacao are the reduction of shade to the lowest amount compatible with due protection from wind; deep and efficient soil drainage; annually forking the land between the trees without injuring the roots any more than is absolutely necessary; mulching the soil; and manuring the trees with a mixture of superphosphate of lime and sulphate of potash.

Eliminating the drone tree, L. B. Scott (Cal. Citrogr., 1 (1916), No. 9, pp. 8, 9, 19, figs. 2).—A popular review of the results secured in California in the improvement of oranges and lemons by bud selection (E. S. R., 33, p. 737; 34, p. 639), including a description of methods employed in making records of the production of individual trees.

The rose annual for 1916 of the National Rose Society, edited by H. R. Darlington (London: National Rose Society, 1916, pp. VIII+164, pls. 35).—This comprises a collection of articles on various phases of rose culture, including some general accounts of rose growing in different parts of the British Empire and elsewhere.

A partial list of plants available for various uses in general landscape planting, A. D. Taylor (Cleveland, Ohio: Author, 1916, pp. 51).—The plant materials listed in this booklet have been included with special reference to

their use in the Northern and North Central States. Concise information is given relative to the correct use of the more prominent species of trees, shrubs, vines, and perennials in ornamental and landscape plantings.

Ornamental gardening in Florida, C. T. SIMPSON (Little River, Fla.: Author, 1916, pp. XIII+198, pls. 40, figs. 3).—A treatise on the decorative plants adapted to Florida and their cultivation, with suggestions for the ornamentation of Florida homes and grounds.

# FORESTRY.

Report of the Maryland State Board of Forestry for 1914 and 1915 (*Rpt. Md. State Bd. Forestry, 1914–15, pp. 77, pls. 7*).—A report on forest activities for the years 1914 and 1915 in which consideration is given to forest fire protection, assistance to owners of woodland, work on the state forest reserves and the state forest nursery, forest and tree planting operations under state supervision, investigational and educational work, and public shade tree work.

The Sequoia and General Grant National Parks, season of 1916 (U. S. Dept. Int., Off. Sec. [Pub.], 1916, pp. 48, figs. 3).—A pamphlet of information relative to the forests in these parks, methods of transportation, camp sites, birds, mammals, and fishes occurring there, rules and regulations, and literature dealing with the parks. See also a note by Hill (E. S. R., 35, p. 242).

The Mesa Verde National Park, season of 1916 (U. S. Dept. Int., Off. Sec. [Pub.], 1916, pp. 48, figs. 5).—An account similar to the above relative to the Mesa Verde National Park.

Manual of instructions for county forest wardens and district forest wardens and information in regard to the prevention and suppression of forest fires, J. E. Babton (Frankfort, Ky.: State, 1915, pp. 31).—Although designed primarily for forest officers this manual contains considerable information of value to the general public in the matter of controlling forest fires.

Forest protection.—I, Protection against animals, R. Hess (Der Forstschutz. Erster Band: Schutz gegen Tiere. Leipsic: B. G. Teubner, 1914, vol. 1, 4. ed., rev., pp. XIII+537, pls. 2, figs. 250).—A text-book, manual, and reference work on forest protection. The present edition has been entirely rewritten by R. Beck. The successive parts of the present volume deal in detail with protection against domestic animals, game, and other wild animals, birds, and insects.

Causes determining the forms of trees, P. Jaccard (Rev. Gén. Bot., 27 (1915), Nos. 321, pp. 257-270, ftg. 1; 323, pp. 335-349; 324, pp. 353-374, ftgs. 2).—Recent experimental and mathematical investigations are said to have substantially confirmed the conclusion formerly reached (E. S. R., 29, p. 342), and to have shown that the forms of tree trunks, those of Picea excelsa in particular, are directly influenced in essential characters, notably in the variations in thickness of the layers of growth, by the exigencies of circulation of water and of nutritive materials. See also a previous note (E. S. R., 34, p. 536). The applicability of the theory of the slow selection of useful variations in this connection is denied.

On the amount of sap discharged by some trees, M. MIYOSHI (Jour. Col. Sci. Imp. Univ. Tokyo, 38 (1916), Art. 1, pp. 14, figs. 4).—Investigations conducted by the author with two species of trees showing high sap pressure, Cornus controversa and Carpinus yedoensis, led to the conclusion that it is impossible to secure accurate results relative to the discharge of sap for a longer time than one bleeding period where the usual method of collecting the sap from an auger hole is followed. A local stoppage in the hole is found to take place inevitably, thus influencing the amount of sap flow.

Pinus longifolia. a silvicultural study, R. S. Troup (Indian Forest Mem., Sylviculture Ser., 1 (1916), No. 1, pp. 126, pls. 33).—The study here reported is based on personal investigations extending over a number of years in most of the important tracts in which P. longifolia forests occur.

The subject matter is presented under the general headings of the distribution, locality, and types of forest; silvicultural characters and requirements; natural regeneration; artificial regeneration; external dangers; fire effects and protection from fire; tending operations; systems of management; and statistical information.

Report on the question of field experiments, with special reference to the execution of tapping experiments on estates, G. E. Coombs (Agr. Bul. Fed. Malay States, 4 (1916), No. 8, pp. 229-242, figs. 4).—The purpose of this report is to present to rubber planters a statement of the general principles which should govern field experiments in tapping rubber.

Chief factors influencing the development of sal seedlings, R. S. Hole (Indian Forester, 42 (1916), No. 7, pp. 335-348, pls. 6).—A summary of some of the chief results of the study recently conducted at Dehra Dun, relative to the factors influencing the development of sal (Shorea robusta) seedlings.

Newfoundland and its forest resources, D. Morris (Jour. Roy. Soc. Arts, 64 (1916), No. 3310, pp. 439-452; Scot. Geogr. Mag., 32 (1916), No. 8, pp. 353-366).—An account is given of the forest areas, principal timber trees, and forest industries in Newfoundland.

Structural timber handbook on Pacific coast woods, O. P. M. Goss and C. Heinmiller (Seattle, Wash.: The West Coast Lumbermen's Assoc., 1916, pp. 289, figs. 38).—A handbook of information relative to the character, strength, durability, and uses of Pacific coast woods. The strength and durability data are based upon tests conducted by the Forest Service of the U. S. Department of Agriculture and other organizations.

The organization of the lumber industry, W. Compton (Chicago: American Lumberman, 1916, pp. X+153, figs. 23).—This comprises an analysis of the influences which have largely determined the recent course and the present level of the prices of lumber in the United States.

#### DISEASES OF PLANTS.

Plant diseases in England and Wales, 1914–15 (Jour. Bd. Agr. [London], 22 (1916), No. 10, pp. 931–939).—This is a statement regarding plant diseases, insect pests, etc., issued in lieu of the annual report, temporarily suspended, of the horticultural branch of the Board of Agriculture.

It is stated that the mild weather in the spring of 1914 induced the summer stages of the American gooseberry mildew at an earlier date than any previously recorded in England and led to an unusually severe attack on the fruit. In 1915, the disease appeared somewhat later and was severe only where long drought had weakened the resistance of the bushes. Timely and proper pruning is supposed to afford complete protection and to benefit the bushes otherwise. This treatment should be carried out in the period between the "soft and the hard condition of the fruit." Fungicides check the disease under favorable conditions, but in no case was it completely killed out by their use. American gooseberry mildew is said to be known in all European countries.

Wart disease is reported to cause loss in over 200 industrial districts. Some potato varieties have now been tested many times and are considered to be completely immune. The number of cases in agricultural districts is very small, but the occurrence of sporadic cases suggests that the disease may be dormant

for a season under certain conditions. Tests with formalin promise little success.

Corky seab is said to be very much localized in England and rare in localities where potatoes are grown in large quantities. In a few cases it has been found in a high degree of intensity, proving as destructive as wart disease. No remedy is known for corky scab, to which every variety of potato appears to be susceptible, but it spreads slowly and does not appear to persist in well cultivated soil.

Silver leaf of plums and apples and apple mildew have been studied to some extent. Dilophia graminis has been discovered on wheat in two localities.

Recent observations on diseases of cultivated plants in Bohemia, A. Kutín (Věstnik 5. Sjez. Ces. Přír., 1915, p. 427; abs. in Bot. Centbl., 129 (1915). No. 15, p. 384).—Observations are recorded on the appearance in Bohemia for the first time of Tilletia lævis, Peronospora jaapiana, and Typhula graminum, and the reappearance, after some years, of Tilletia secalis. Sclerotinia trifoliorum has been noted in new localities, and Sphærotheca mors-uvæ appears to have attained wide if not universal distribution.

Cryptogamic parasites of cultivated plants in and near the Province of Turin in 1913, P. Voglino (Ann. R. Accad. Agr. Torino, 57 (1914), pp. 159-174; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 6, pp. 881, 882).—This is an arrangement of the data as collected in 1913 regarding weather and regarding cryptogamic parasites of plants in this region. The diseases noted, while encouraged in some degree by the spring rains, were later held in check by the dryness of the summer season.

Recent contributions to our knowledge of the genus Gymnosporangium, F. D. Kern (Abs. in Science, n. ser., 43 (1916), No. 1106, p. 364).—The author reviews information regarding the genus Gymnosporangium, supplemental to his previous report (E. S. R., 27, p. 424). Among the more notable points brought out are the reporting of another aecial host outside of the Rosales, the finding of teliospores in the species possessing uredinia, studies of the effects produced by the host on the morphology of the fungi, and active investigations of the species causing diseases of economic importance.

Cultures of Uredineæ in 1915, J. C. ARTHUR (Mycologia, 8 (1916), No. 3, pp. 125-141; abs. in Science, n. ser., 43 (1916), No. 1106, p. 363).—With this report, the fourteenth of a series continued by the author since 1899 (E. S. R., 32, p. 750) on the culture of plant rusts, it is proposed to end the series of investigations.

Besides notes on species giving negative results owing to inadaptation of the racial material used, an account is given of successful cultures supplementing work previouly reported in case of 8 species named and a list of 4 species now reported on for the first time.

White speck disease of leaves, C. von Tubeuf (Naturw. Ztschr. Forst. u. Landw., 13 (1915), No. 10, pp. 469-475, figs. 3).—The author describes a peculiar leaf decoloration, which is said to be associated with the absence of chlorophyll, starch, and generally plasma in the palisade cells. The affected areas are small but thick. A list is given of woody plants and one of herbaceous plants known to exhibit this phenomenon.

Further evidence that crown gall of plants is cancer, E. F. SMITH (Science, n. ser., 43 (1916), No. 1121, pp. 871-889).—This is a paper read before the Washington Academy of Sciences, in which the author presents further evidence that crown gall of plants is cancer, and that cancer in plants, because of its variable form and its bacterial origin, offers strong presumptive evidence both of the parasitic origin and of the essential unity of the various forms of cancer occurring in man and animals.

Concerning certain peculiar tissue strands in a Protomyces gall on Ambrosia trifida. A. Stewart (Abs. in Scie. c., n. scr., 48 (1916). No. 1106, pp. 365, 366).—The stems of the great ragweed are said to be sometimes infected by P. andinus, causing the formation of large galls. These usually occur just above the ground, but often higher on the stem, sometimes as much as 2 ft. above the galls which are located near the roots. Both kinds of galls have essentially the same histological structure, the deeper portions near the pith having peculiar tissue strands which are similar in some respects to the tumor strands found in certain plants affected with the crown-gall organism. The fact that the abnormalities in the tissues of the host plants are found in or near to the pith indicates that the stems become infected when quite young. This is offered as a possible explanation as to how the upper galls of the stems are produced.

Acid sprays as related to scorching, L. Degrully (Prog. Agr. et Vit. (Ed. VEst-Centre), 37 (1916), No. 16, pp. 365-367).—It is stated that while low concentrations, for example 1 per cent copper sulphate and 0.4 per cent carbonate of soda in Burgundy mixture, are rarely dangerous, the same proportions maintained in higher concentrations may prove very injurious to foliage. With 2 per cent sulphate and 0.9 per cent carbonate, the foliage seldom, if ever, scorches, with 2 per cent sulphate and 0.875 carbonate rarely, while with 2 per cent sulphate and 0.75 carbonate the preparation is very strongly acid, and is not ordinarily to be recommended for use after the blooming period. Bordeaux mixture containing 1 per cent copper sulphate and 0.5 per cent lime (sometimes contaminated by the presence of magnesia) practically always gives an alkaline solution.

The powdery mildews of Avena and Triticum, G. M. Reed (Missouri Sta. Research Bul. 23 (1916), pp. 3-19).—In previous publications (E. S. R., 21, p. 641), the author showed that the morphological species, Erysiphe graminis, consists of a large number of different races. In a subsequent paper (E. S. R., 27, p. 545), the results of infection experiments with the powdery mildew of wheat were given. The present paper gives the results of a large number of additional experiments with E. graminis on Avena and Triticum. Seed of these genera was obtained from various sources, 165 varieties of wheat being tested with reference to their susceptibility to the fungus. A great majority of these varieties proved quite susceptible. All of the eight recognized types or species of Triticum contained susceptible varieties, and only a few distinctively resistant varieties were found.

An account is also given of the physiological race of *E. graminis* which occurs on species of Avena. Tests have been made of 41 varieties belonging to 17 species, and a great majority have proved susceptible to the oat mildew. It was also found that the wheat mildew readily passed over to certain species of Ægilops and the oat mildew to *Arrhenatherum avenaceum*.

A Phytophthora on oats, J. McMurphy (Science, n. ser., 43 (1916), No. 1111, p. 534).—The author reports observing on leaves of oats in California a species of Phytophthora which is said to be similar to P. colocasiæ. A more extended study, however, is considered necessary to determine the specific rank of the fungus. The markings produced on the oats by the fungus may appear as spots or stripes along one or both margins of the leaf, or as a stripe down the center. The diseased areas become yellowish and then whitish when conidia are abundant. Later these areas, which sometimes have a water-soaked appearance, may become brown or reddish-brown, and the parts shrivel and dry up.

Seed treatment tests, 1914, L. HILTNER (Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 13 (1915), No. 6-7, pp. 65-90).—This deals in considerable detail with experiments carried out in Bavaria during 1914 by steeping seed grain of

winter rye and wheat in solutions containing corrosive sublimate as a protection against Fusarium and other fungi. The variety, degree of attack, germinability, grain weight, and fall and spring conditions are noted in the tables given.

The relation of the seed stock to the control of bean anthracnose and bean blight, J. H. Munch (Abs. in Science, n. ser., 43 (1916), No. 1106, p. 365).—On account of the failure of fungicides in the control of these diseases and pending the experiments on the growing of seed for Michigan planting in western States where anthracnose is unimportant, the author recommends the planting of varieties of beans of high productivity, so that the losses in ordinary years will be so decreased as not to be burdensome to the industry. Such a variety, it is said, has been found in the Early Wonder, which matures early and is very productive even under severe disease and weather conditions.

Angular leaf spot of cotton, F. M. Rolfs (South Carolina Sta. Bul. 184 (1915), pp. 3-30, pls. 8).—An account is given of an investigation of the angular leaf spot of cotton, the first description of which appears to have been given by Atkinson (E. S. R., 3, p. 7). According to the author's investigations, this disease is believed to be common in every cotton-growing State in the Union.

The disease produces angular spots on the leaves, and blackened areas are formed on the stalks and branches. It also attacks young bolls. Young seedling plants usually suffer most severely and in many cases are killed outright. The cause of the disease is said to be *Bacterium malvacearum*, which survives the winter in and on the seed and also on the lint. Delinting the seed with sulphuric acid or treating the seed with hot water at 72° C. for 18 minutes greatly reduced the number of infected plants. Delinting the seed and spraying the plants six times with Bordeaux mixture resulted in the production of 98 per cent of sound plants. This method of treatment would probably be practicable where plants are grown for seed production.

Anthracnose (Colletotrichum lagenarium) a serious disease of cucurbits, J. J. Taubenhaus (Abs. in Science, n. ser., 43 (1916), No. 1106, p. 366).—A preliminary report is given of investigations of anthracnose of watermelons, cantaloups, cucumbers, and other cucurbits. These are said to be seriously affected in Delaware, and similar conditions are reported in New Jersey, Maryland, and Virginia. The disease attacks the fruit, particularly in case of the watermelon, and also causes a serious leaf spot and a blight and canker of the vines. The attacks are severest on the watermelon crop in its second successive year. On this account, growers are forced to practice rotations of six years or longer.

Inoculations have shown that the anthracnose from the watermelon, cantaloup, cucumber, citron, and ornamental gourd is identical, the disease being readily transferred from one host to another. Investigations are said to be in progress to determine the life history of *C. lagenarium*, its relationship to the various hosts, and to other species of Colletotrichum, especially *C. lindemuthianum*.

Potato diseases and their control, E. C. STAKMAN and A. G. Tolaas (Minnesota Sta. Bul. 158 (1916), pp. 3-47, figs. 28).—Descriptions are given of a considerable number of parasitic and nonparasitic diseases of potato, with suggestions for their control. For the leaf diseases, Bordeaux mixture is recommended, while wilt diseases and stem rot may be controlled by roguing fields, by selecting and disinfecting seed, and by rotating crops. Experiments conducted during 1914 and 1915 showed that the average yield of potatoes per acre was increased 56 bu. in 16 fields by seed selection and disinfection. Spraying experiments which have been carried on for seven years gave an average annual increase of 63 bu. per acre of early potatoes sprayed 3 times with Bordeaux mixture or of late potatoes sprayed 4 times.

Potato disease, Korff (Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 13 (1915), No. 8, pp. 109-111, fics. 2).—Brief reference is made to a leaflet issued by the Institute for Agricultural Botany at Munich, dealing with leaf disease and Phytophthora tuber rot of potato and the control of both these troubles by the timely use of copper sprays.

Marasmius on sugar cane, J. R. Johnston (Mycologia, 8 (1916), No. 2, p. 115).—Referring to the description given by Fulton (E. S. R., 19, p. 956) of the fungus designated by him as M. plicatus, causing root disease of sugar cane in Louisiana, the author states that his own specimens on sugar cane from Louisiana and Texas answer rather to the description of M. stenophyllus (M. semiustis), said to have been reported on bananas in many West Indian islands but not before on sugar cane.

Effect of colored light on the mosaic disease of tobacco, G. H. Chapman (Science, n. ser., 43 (1916), No. 1111, pp. 537, 538).—The author reports some investigations conducted to verify the conclusions of Lodewijks (E. S. R., 24, p. 648) that blue light offers a cure for the mosaic disease of plants.

The diseased leaves of a number of tobacco plants were covered with hoods composed of different colored cloth, and it was found that when blue light was used there was a suppression of the leaf color variation more or less permanent in character. With a single exception, the treated plants showed no typical symptoms of the disease for at least two weeks after the removal of the hoods. That the disease was, however, not controlled was shown by the inoculation of healthy plants with the juice of the treated plants, as this produced the disease in nearly every case. This is taken to show that the active principle of the disease is present in the apparently normal, fully recovered leaves and that it is highly infectious.

The leaf spot disease of tomato, E. Levin (Michigan Sta. Tech. Bul. 25 (1916), pp. 5-51, pls. 9, figs. 2).—This bulletin gives the results of experiments on the leaf spot disease of tomato, due to Septoria lycopersici, and recommendations for its control. While many investigators have reported this fungus as causing the leaf spot disease of tomato, its parasitism was definitely proved by the author's investigations. The morphological, ecological, and physiological relations of the organism are described at some length, and control measures, which include the planting of clean seedlings in clean soil and thorough spraying with Bordeaux mixture, are recommended.

A canker of apple caused by Plenodomus fuscomaculans, G. H. Coons (Abs. in Science, n. ser., 43 (1916), No. 1106, p. 364).—A serious canker of apple is said to occur in some orchards in northern Michigan. The canker is characterized by elongated lesions which are commonly accompanied by a checking of the bark into small squares or rectangles. The lesions are said to extend along the limb, commonly on the underside. In the older cankers the killed bark drops off, leaving the bare wood.

The causal relation of the associated organism has been shown by inoculation experiments, and the results of a study of its physiological relations have been previously noted (E. S. R., 34, p. 647). Successful inoculations were obtained on the limbs of Wealthy, Duchess, Jonathan, and Ben Davis apples, as well as on the Hyslop crab. Other standard varieties seem more resistant. The fungus has also been successfully inoculated into pear, small cankers having been formed, but no inoculations have succeeded on apple leaves.

The disease, it is claimed, may be successfully controlled by the means commonly advised for apple canker.

Fungi producing the heart rot of the apple, B. O. Dodge (Mycologia, 8 (1916), No. 1, pp. 5-15, pls. 4; abs. in Science, n. ser., 43 (1916), No. 1106, p. 366).—Living apple trees at Litchfield, Conn., are reported as being infected

with *Polyporus admirabilis* during August. Apple trees in the eastern United States are said to be more commonly attacked by another type of Polyporus. *P. galactinus* or *P. spumeus malicola* is the species ordinarily found in old orchards of the New England States, while *P. fissilis* is reported as attacking trees in Virginia.

Monilia on fruit trees, G. Voss (Flugbl. Samml. Pflanzenschutz, K. Landw. Akad. Bonn-Poppelsdorf, No. 7 (1915), pp. 4, figs. 5; abs. in Bot. Centbl., 129 (1915), No. 22, pp. 574, 575).—A description is given of symptoms and results of attack on fruit trees by the Monilia forms of Sclerotinia cinerea, S. fructigena, and S. laxa. Protective measures include the early removal and destruction of all affected parts, including fallen fruits and dead wood.

Apricot fruit spots, J. T. Barrett (Univ. Cal. Jour. Agr., 3 (1916), No. 8, pp. 346-349, figs. 3).—Descriptions are given of brown rot of apricot, caused by Puccinia pruni-spinosæ; of Coryneum fruit spot, due to C. beijerinckii; and of scab or black spot of apricot, caused by Cladosporium carpophilum. It is said to be easy to confuse some of these, especially in their early stages.

The reciprocal influence between mycotrophic roots of different plants, L. Petri (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), II, No. 11, pp. 536-539, fig. 1).—Describing the results of growing oaks and olives in close proximity, the author holds that the injury often observed to be suffered by the olive in this relation may be due to the impoverishment of the soil by the oak or to an eventual root rot caused by a Dematophora developing on the subterranean residues of the oak growths, and not to the proximity of the mycorrhiza on the oak. The possible bearing in this connection of facts previously observed (E. S. R., 26, p. 849) is discussed.

Formalin as a spray against American gooseberry mildew (Deut. Landw. Presse, 42 (1915), No. 36, p. 329; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 7, p. 999).—B. Panten of Kazmierz, Posen, reports that a 1 per cent solution of 40 per cent formalin, thoroughly applied in the early spring and again before the period of blooming, effectively controlled American gooseberry mildew.

A new fungicide for use against American gooseberry mildew, J. V. EYRE and E. S. Salmon (Jour. Bd. Agr. [London], 22 (1916), No. 11, pp. 1118-1125; abs. in Gard. Chron., 3. ser., 59 (1916), No. 1523, p. 132).—It is stated that an ammonium sulphid solution containing 0.18 per cent of sulphur can be recommended for commercial use on an experimental scale for the purpose of protecting the fruit of gooseberries against the mildew. Lime-sulphur wash should be employed for early sprayings until such time as its use would affect the marketing of the berries, when the ammonium sulphid solution should be substituted. It is stated that solutions of liver of sulphur at the strength usually considered as fungicidal are inefficient against the disease, while concentrations which are fungicidal cause such severe scorching of the gooseberry bushes as to preclude their use in this connection.

Notes on the dying of citrus trees, A. H. Benson (Queensland Agr. Jour., n. ser., 5 (1916), No. 5, pp. 258-266).—Concerning the dying of citrus trees in different sections, a progress report made by F. Smith is quoted at some length with comments thereon. The trouble is considered due to causes other than soil conditions, and as more probably parasitic in character, though possibly very complex in origin. Age and living conditions of the trees are discussed in this connection. It is thought possible that irregularity in growth may prove to be very important.

Descriptions are given also of other twig, collar, and root troubles.

Fungi attacking cultivated and wild Orchidaceæ and their control, G. Lindau (Gartenflora, 64 (1915), Nos. 21-22, 23-24; Orchis, 9 (1915), Nos. 7, pp. 171-178; 8, pp. 181-203).—Descriptive lists are given including many Uredineæ, Ascomycetes, and imperfect fungi attacking orchids in many widely separated regions of the world.

Black canker in young chestnut trees and nurseries, G. Briosi and R. Farneti (Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat., 5. ser., 24 (1915), I, No. 2, pp. 98–105; abs. in Internat. Inst. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 4, pp. 637, 638).—It is stated that black canker may attack not only adult chestnut trees but also very young plants and even germinating seed, so that a considerable epidemic of this disease may occur in the nursery. The disease is said to be due to infection and not to soil exhaustion.

Studies on diseases of oak, E. MÜNCH (Naturw. Ztschr. Forst u. Landw., 13 (1915), No. 11-12, pp. 509-522, figs. 6).—Previous reports (E. S. R., 24, p. 52) are followed up by an account of a study of Polyporus igniarius, the cause of white rot of oak, more particularly as regards its rate of progress in canker formation and the different rates of progress in cambium, bast, and sapwood.

Monograph on oak mildew, F. W. Neger (Naturw. Ztschr. Forst u. Landw., 13 (1915), No. 11-12, pp. 544-550, figs. 2).—The article previously noted (E. S. R., 33, p. 745) is here supplemented by an account of tests with the Ofdium causing oak mildew on species of Rubus, from which the author concludes that under appropriate conditions a fungus may flourish and even produce spores on a host normally foreign thereto, and that on the basis of studies involving such cases errors of identity may be promulgated. The overwintering of oak mildew is also discussed.

A new disease of walnuts, H. Memmler (Gartenwelt, 19 (1915), No. 53, pp. 623, 624, fig. 1).—A nut spot of walnut is described as apparently new, but the cause of the trouble has not yet been determined.

Note on western red rot in Pinus ponderosa, W. H. Long (Mycologia, 8 (1916), No. 3, pp. 178-180).—Reporting on the study of the heart rot of western yellow pine, called western red rot in order to distinguish it from a very similar heart rot called red heart or red rot (Trametes pini) common in many species of conifers, the author states that the western red rot has three developmental stages. The first shows reddish to dark brown areas in the heartwood which is still firm, the second a whitish or gray color with more or less delignification, and the third a disappearance of much of the heartwood and a very brittle condition of the particles which remain.

This fungus never forms the brown, woody, perennial fruiting bodies on living pine trees that *T. pini* does but forms annual fruiting bodies which usually develop as white encrusting layers on the underside of logs. The pileate form of the fungus resembles very closely *Polyporus ellisianus* (*Tyromyces ellisianus*) and is thought to be specifically identical therewith. The rot is very common throughout the western yellow pine regions of Arizona and New Mexico, and is known to occur in Vermont, New Jersey, Washington, Idaho, and South Dakota.

The fungus enters the living tree, passing through the sapwood, then the heartwood of dead branches, then down into the heartwood of the living tree. During the black jack stage, *i. e.* when not over the age of 150 years, the trees are practically free from this rot. It is, however, exceedingly common in the older trees on account of the dead branches, this factor favoring a short forest rotation. Thin soils on steep southern or eastern slopes, where growth conditions are poor, seem to encourage western red rot.

Laboratory tests on the durability of American woods.—I, Flask tests on conifers, C. J. Humphrey (Mycologia, 8 (1916), No. 2, pp. 80-92, pl. 1).—This work has been in progress for about three years. In most cases both heart and sap wood were used. The blocks cut from logs brought to the laboratory green were placed in flasks, and inoculated plentifully with bean-pod cultures of Lentinus lepideus, and kept 4, 8, or 12 months. The results are tabulated and some are discussed.

The order of resistance in case of the highest three, as measured by the smallness of loss in weight by the heartwood during 12 months, was California juniper (3.3 per cent), white cedar (5.4 per cent, sapwood 7.7 per cent), and white pine (8.8 per cent). The loss for both heart and sap wood of fir, spruce, hemlock, and most of the pine during this period ranged within or around 60 to 70 per cent.

Further tests on heartwood of some of the species are considered necessary before safe comparisons can be made.

#### ECONOMIC ZOOLOGY-ENTOMOLOGY.

A history of British mammals, G. E. H. Barrett-Hamilton and M. A. C. Hinton (London: Gurney & Jackson, 1916, vol. 2, pt. 18, pp. 553-600, pls. 3, figs. 2).—A continuation of the Muridæ of the Rodentia, previously noted (E. S. R., 35, p. 252), in which the harvest mouse (Micromys minutus) and the black or ship rat (Epimys rattus) are considered.

Rats and rat riddance, E. H. FORBUSH (Agr. of Mass., 62 (1914), pp. 169-251, pls. 12, figs. 19).—This account deals somewhat at length with the biology of rats, their economic importance, and the various means by which they may be held in check.

Description of a new pine mouse from Florida, A. H. Howell (Proc. Biol. Soc. Wash., 29 (1916), pp. 83, 84).

Fumigation of animals to destroy their external parasites, W. Moore (Jour. Econ. Ent., 9 (1916), No. 1, pp. 71-80, figs. 2) —The author has met with success in the fumigation of animals with nitrobenzene, the insects being killed without injuring the host.

Report of the entomologist of the Arizona Commission of Agriculture and Horticulture for the year ended June 30, 1915, A. W. Morrill (Ariz. Com. Agr. and Hort. Ann. Rpt., 7 (1915), pp. 9-50, pls. 6, figs. 18).—The first part of this report (pp. 9-26) relates to the inspection of plant, fruit, and seed importations; the provision for the terminal inspection of plant products shipped by parcel post; inspections of orchards, nurseries, and fruit products of the State; alfalfa weevil protection; and insect control and eradication. The second part (pp. 27-46) consists of notes on the important insects of the year under the headings of pests of deciduous fruits and vines, citrus and olive pests, pests of field and forage crops, vegetable crop pests, cotton pests, and a range plant pest (Trirhabda canadensis). Part 3 (pp. 47-50) describes two vegetable pests to be guarded against, namely, dodder, a menace to the alfalfa seed-growing industry, and citrus canker.

Among the more important insects mentioned are the steel-blue grapevine flea-beetle (Haltica carinata), which was an important pest in the Salt River Valley during the spring; the clover mite, which did some damage to almonds in an orchard near Mesa, Ariz.; the flat-headed apple-tree borer, which was unusually destructive to peach, apricot, and plum trees in the Salt River Valley; the wheat or flower thrips (Frankliniella tritici), which was particularly injurious to blackberries and found also in the blossoms of the olive in the spring of 1915; two walnut borers (Prionus californicus [?] and Euzophera æglælla);

the common alfalfa grasshopper (Melanoplus differentialis), the three-cornered alfalfa hopper (Stictocephala festina), and the clover stem borer in alfalfa; the Mexican moth borer (Diatrwa lineolata [?]; billbugs injurious to sugar cane (Sphenophorus phæniciensis); the potato stalk borer which is becoming of increasing importance in southern Arizona; the two-spotted red spider (Tetranychus bimaculatus); the cotton leaf miner (Bucculatrix thurberiælla); a capsid closely related to the tarnished plant bug; etc.

First biennial report State Crop Pest Commission of West Virginia, March 1, 1913, to June 30, 1914, W. E. Rumsey et al. (Crop Pest Com. W. Va. Bien. Rpt. 1 (1913-14), pp. 132, figs. 38).—This consists of the report of the state entomologist, and discussions of inspection work; nursery registration; cedar rust eradication in Berkeley County; distribution, abundance, injury, etc., of periodical cicada in 1914; control of apple and peach tree borers; chestnut blight eradication work, etc. Several bulletins issued by the commission, viz, (1) State Crop Pest Law, Rules and Regulations of the Commission; (2) Orchard Inspection, Apple Rust, Chestnut Bark Disease; (3) The San José Scale; and (4) The Periodical Cicada in West Virginia in 1914 and The Green Apple Aphis and Other Plant Lice are included. The text of a proposed crop pest law to supersede the present statutes is appended.

Insects in the Virgin Islands, H. A. Ballou (Agr. News [Barbados], 15 (1916), No. 361, pp. 74, 75).—A brief account based upon a collection of insects made by the curator of the experiment station in the Virgin Islands.

Insect pests of plants, Northern Territory of Australia, G. F. Hill (Bul. North. Ter., Aust., No. 13 (1915), pp. 16).—A brief account is given of the more important insect pests of plants in Northern Territory, Australia, including a description of the life history, natural enemies, and methods of control of each.

Insects infesting the cotton plant in Trinidad, F. W. URICH (Bul. Dept. Agr. Trinidad and Tobago, 15 (1916), No. 1, pp. 18, 19).—This paper briefly considers eleven species of insects, their common names, natural enemies, economic status, and control measures.

Some insects of Solanum carolinense and their economic relations, M. P. Somes (Jour. Econ. Ent., 9 (1916), No. 1, pp. 39-44).—The author reports observations of the sudden development of the berytid bug Jalysus spinosus as a serious pest of the tomato. Previous to this time S. carolinense had served as its food plant. It is stated that during the past two years this insect has worked widely through Missouri and in some districts where tomato raising for canneries is of importance has occasioned serious loss.

Sesia rileyana occurs in large numbers on S. carolinense. Boring into the central part of the stem it works downward to the roots, and passing down one of the main branches at about the time it matures bores out of the root into the soil. A test transfer of larvæ from the horse nettle to tomato and potato succeeded.

A tortoise beetle (Cassida pallidula), a tingitid bug (Gargarphia solani), the potato stalk borer, the fleabeetles Epitrix fuscula and E. cucumeris, the common sphingids Phlegethontius carolina and P. quinquemaculata, and a lygeid bug (Ischnodemus fallicus), which attack cultivated crops, are reported as occurring on S. carolinense.

Rhodesian citrus pests, R. W. Jack (Rhodesia Agr. Jour., 13 (1916), Nos. 1, pp. 69-83, pls. 3; 2, pp. 215-233, pls. 6).—A brief summary of the insect enemies of citrus in Rhodesia and measures for their control.

Lepisma saccharina (?); its life history and anatomy and its gregarine parasites, J. W. Cornwall (Indian Jour. Med. Research, 3 (1915), No. 1, pp. 116-131, pls. 6).—Accounts of the biology of the common silver fish of India and of two distinct gregarines parasitic in its gut.

A new Physothrips (Thysanoptera) from Uganda, with a note on Physothrips antennatus, J. D. Hoop (Canad. Ent., 48 (1916), No. 4, pp. 130-132, fig. 1).

Heliothrips hæmorrhoidalis injurious to ornamental plants in the Province of Buenos Aires, Argentina, C. Lizer (Agronomia [Buenos Aires], 6 (1915), No. 36-38, pp. 9-11, figs. 3; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 11, pp. 1549, 1550).—The author records injury to Pelargonium peltatum and Lagerstræmia indica by this thrips.

Eradication of the bedbug by superheating, W. A. Ross (Canad. Ent., 48 (1916), No. 3, pp. 74-76).—This paper records the extermination of Cimex lectularius from a 2-story, 8-room frame house, heated with a hot-air furnace and kitchen and parlor stoves, in which the temperature of three of the rooms was raised as high as 140, 158, and 162° F., respectively. Very satisfactory results were obtained, the pest being fully eradicated and the house furniture not damaged to the slightest degree. It is thought that the temperature obtained was unnecessarily high and that the superheating would have been equally effective if the temperature had been maintained between 120 and 130°.

Life history notes on Apateticus cynicus and A. maculiventris, R. D. Whitmarsh (Jour. Econ. Ent., 9 (1916), No. 1, pp. 51-53).—These notes relate to the biology, including the predatory habits, of two stink bugs. The former, the largest and most common predacious species, unlike the latter, is single brooded.

The distribution of the periodical cicada in **O**hio, H. A. Gossard (*Jour. Econ. Ent.*, 9 (1916), No. 1, pp. 53-59, figs. 3).—A report of the present distribution of the broads of 1906, 1914, and 1915 in Ohio.

Notes on the tomato psylla, H. Compere (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 5, pp. 189-191, figs. 3).—These notes relate to the biology and control of Paratrioza cockerelli, found by the author infesting the Jerusalem cherry (Solanum capsicastrum) at Sacramento and San Francisco. The solanums at the latter place were rendered worthless.

Concerning problems in aphid ecology, Edith M. Patch (Jour. Econ. Ent., 9 (1916), No. 1, pp. 44-51).—A discussion of some of the important ecological problems.

The present state of our knowledge of the biology of the vine phylloxera, B. GRASSI (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 10, pp. 1269-1290).—This article reviews the status of knowledge of the biology of the grape phylloxera previous to 1905, and discusses the advances resulting from researches made since that date and the question as to the existence of different races of phylloxera.

Modern views of the control of the vine phylloxera, B. Grassi (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1553-1571).—The author discusses the importance of control and methods usually employed, the method of control in Italy, the advisability of continuing the campaign, the manner of dispersal of the phylloxera, and the proposed method of control.

A nematode parasite of root aphids, J. J. Davis (*Psyche*, 23 (1916), No. 2, pp. 39, 40, ftg. 1).—The author reports having found apterous viviparous and oviparous individuals of a new species of Ancecia infested with nematodes at West Lafayette, Ind.

Two newly-established scale insects, E. O. Essig (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 5, pp. 192-197, figs. 6).—The camellia scale (Pulvinaria floccifera) and the dictyospermum scale (Chrysomphalus dictyospermi) are reported to have recently become established in limited districts in California.

On the structure and biology of Tachardia lacca, with observations on certain insects predacious or parasitic upon it, A. D. Imms and N. C. Chatterjee (Indian Forest Mem., Forest Zool. Ser., 3 (1915), No. 1, pp. 42, pls. 8).— Historical notes are first given, followed by a discussion of the systematic position of this coccid, the secretion and chemical composition of lac, its life history, distribution in India, and chief food products, together with descriptions of its several stages, habits, insect enemies, etc. A bibliography of 29 titles is included.

The rice stem borer in the Konkan, R. S. Kasargode and V. G. Deshpande (Dept. Agr. Bombay Bul. 69 (1915), pp. 18, pl. 1).—This is a detailed account of Schoenobius bipunctifer, a lepidopteran which occurs throughout the greater part of the Indian rice area. It is the source of a large percentage of the insect injury to rice, which is rarely less than 10 per cent of the crop and may be as high as 60 per cent. The caterpillar attacks the plant at some point in the stem, which soon withers and turns white. Six days are required for its embryonic development, 27 for the larva, and 9 for the pupa, or a total of 42 days for the life cycle.

Climate and variations in the habits of the codling moth, E. P. Felt (Jour. Econ. Ent., 9 (1916), No. 1, pp. 107-110).—It is the author's opinion that, if conditions obtaining in New York during the past two or three years are reliable criteria, climatic differences exert a considerable influence upon the habits and the type of injury caused by the codling moth.

Notes on crambids, G. G. AINSLIE (Jour. Econ. Ent., 9 (1916), No. 1, pp. 115-119).—Miscellaneous notes relating to the methods of rearing, etc., of crambids.

The control of the grape berry worm (Polychrosis viteana), W. H. Goodwin (Jour. Econ. Ent., 9 (1916), No. 1, pp. 91-106).—Substantially noted from another source (E. S. R., 35, p. 358).

Preliminary studies of the biological control of the grapevine pyralid (Œnophthira pilleriana), F. Schwangart (Naturw. Ztschr. Forst u. Landw., 13 (1915), Nos. 8-9, pp. 380-408; 11-12, pp. 522-541).—The first part of this paper (pp. 380-398) deals with parasites of Œ. pilleriana, particularly the dipterans Prosopodes fugax, Nemorilla maculosa, Gymnoparea (Actia) pilipennis, and Cyrtoneura stabulans. The second part (pp. 398-408, 522-534) consists of a discussion of the parasites of Hyponomeuta and their relation to the vine leaf rollers (Œ. pilleriana, Clysia ambiguella, and Polychrosis botrana), and the third part (pp. 534-541) comprises conclusions, etc.

The pilotaxy of Anopheles, S. R. Christophers (Indian Jour. Med. Research, 3 (1915), No. 2, pp. 362-370, pl. 1).—This article deals with the more important cheete of Anopheles.

The male genitalia of Anopheles, S. R. Christophers (Indian Jour. Med. Research, 3 (1915), No. 2, pp. 371-394, pls. 6).—An anatomical study which includes descriptions and drawings of the genitalia of most of the oriental species of Anopheles and of such others as were available. The author considers the genitalia to be the most satisfactory means for classifying the group.

Dasyneura ulmea, a new elm pest, J. S. Houser (Jour. Econ. Ent., 9 (1916), No. 1, pp. 82-84, fig. 1).—The author reports that this itonidid is the source of injury to elms in Ohio. Its attack results in the formation of from 1 to 20 aborted bud galls, usually at the twig tips, which cause a check in the branch development and an ultimate stunting and malformation of the tree.

A new Phanurus from the United States, with notes on allied species, A. A. GIRAULT (Canad. Ent., 48 (1916), No. 5, pp. 149, 150).—Phanurus emersoni n. sp., reared from tabanid eggs at Dallas, Tex., and three allied species are described.

Studies in flies.—Chætotaxy and pilotaxy of Muscidæ and range of their variability in the same species, P. R. Awati (*Indian Jour. Med. Research*, 3 (1915), No. 1, pp. 135-148, pls. 3, figs. 6).—The author's conclusions in regard to the importance of chætotaxy in Musca are as follows:

"It is very unreliable and hence of little use in classification. The number of bristles on the head is very variable in the same species; their arrangement, however, in some cases seems to be specific, as in the case of the facial bristles. The thoracic bristles show generic variations and hence are important in distinguishing Musca from other genera of the same family."

New genera and species of Australian Muscoidea, C. H. T. Townsend (Canad. Ent., 48 (1916), No. 5, pp. 151-160).

The development and auto-destruction of house flies in horse manure, E. ROUBAUD (Compt. Rend. Acad. Sci. [Paris], 161 (1915), No. 11, pp. 325-327).—The author reports investigations carried on at the central laboratory of the army.

He first calls attention to the fact that horse dung is the best medium for the development of house flies, it being estimated that the dung from a single animal is sufficient for the development in summer of from 40,000 to 50,000 per month, or from 160,000 to 200,000 from June to September. It appears that after scarcely 24 hours fermentation definitely protects the dung against oviposition therein. The use of certain antiseptics and larvicides, such as borax, solutions of cresyl, and ferric and ferrous sulphates, retards fermentation, thus prolonging the period in which oviposition may take place from one to two days, and in this way multiply the chances of infestation of the dung. By the end of the sixth day manure placed in heaps had apparently been vacated by the larvæ, which had migrated for pupation.

Larvæ of the house fly placed in manure at a temperature of 50° C. (112° F.) exposed to the gas formed by fermentation die in three minutes. In direct contact with the gas at a temperature of 51° death takes place in one minute, at 59° in from five to seven seconds, and at 60° in from four to five seconds.

Soluble poisons in the poisoned bait spray to control the adult of the apple maggot (Rhagoletis pomonella), H. H. P. Severin (Maine Sta. Bul. 251 (1916), pp. 149-168, fig. 1).—Experiments conducted during 1914 and 1915 are reported.

No conclusions can be drawn on the effectiveness of the poisoned bait spray from any of the experiments performed during 1914 due to the fact that the different soluble poisons scorched the leaves and therefore insoluble arsenicals were then substituted. A series of experiments with different amounts of soluble poisons, such as potassium and sodium arsenate and sodium arsenite, show that as small a quantity as 0.25 oz. of these insecticides dissolved in boiling water and then added to 3 gal. of water with one pint of molasses will burn the foliage of the apple trees.

"In 1915, during a very rainy season, the results obtained with three applications of the poisoned bait spray containing a soluble poison dissolved in diluted molasses [potassium arsenate 0.75 oz., molasses 1 pint, and water 3 gals.], showed that the infestation varied from 0 to 20 per cent in orchards situated away from the margin of the experimental area, and from 32 to 57 per cent in orchards near untreated trees. An even distribution of the droplets over the foliage is more effective than spraying the trunk, large limbs, and foliage of the lower branches. The number of applications necessary to insure good results can not be stated with this work still in its experimental stage. In orchards where tent caterpillars have practically stripped or partially defoliated the trees the poisoned bait with the use of a soluble poison can not be advocated.

In orchards where tent caterpillars are controlled, defoliation caused by spray injury is far less than the damage caused by these pests in neglected orchards. Our experience shows that after fruit growers have been convinced of the results obtained by the use of the poisoned bait spray, many prefer sound fruit even if burned foliage is the necessary price.

"The fruit fly remedy has been a complete failure in the control of the pest under town conditions. With four applications of the spray the infestation varied from 4 to 98 per cent."

Dangerous hard backs, H. A. Ballou (Agr. News [Barbados], 15 (1916), No. 359, pp. 42, 43, figs. 5).—An account of the more important lamellicorn grubs occurring in the West Indies.

Second report on insecticides for the control of the Colorado potato beetle (Leptinotarsa decemlineata), L. B. SMITH (Virginia Truck Sta. Bul. 17 (1915), pp. 369-376).—This paper gives the results of the second season's experiments in the control of the Colorado potato beetle. These results are said to confirm the more important points of the work done the previous season (E. S. R., 33, p. 358).

The mixture of homemade Bordeaux 50 gal., arsenate of lead 4 lbs., and Paris green 1 lb., continued to give excellent results. Arsenite of zinc paste at the rate of 2 lbs. to 50 gal. of Bordeaux also proved very efficient. Calcium arsenate was tried this year and the results indicate that it may prove valuable for the purpose. Several of the proprietary insecticides that were used gave returns that compared favorably with the home-prepared mixtures in efficiency. The price of arsenic oxid varied according to the form in which it was obtained, costing  $24\frac{1}{3}$  cts. per pound in the calcium arsenate powder and  $51\frac{2}{3}$  cts. in powdered lead arsenate.

Sulphur-arsenical dusts against the strawberry weevil (Anthonomus signatus), T. J. Headlee (Jour. Econ. Ent., 9 (1916), No. 1, pp. 84-89, fig. 1).—Substantially noted from another source (E. S. R., 35, p. 364).

Life history of the pecan twig girdler, S. W. BILSING (Jour. Econ. Ent., 9 (1916), No. 1, pp. 110-115).—The eggs of Oncideres texana hatch in from 17 to 30 days after deposition. The larvæ then burrow in the girdled twigs until the following summer, or for a period of from 288 to 328 days. Pupation takes place during the latter part of August and the first part of September, the pupal stage which lasts from 12 to 14 days being passed in the larval burrow.

It was found that where forests are located near a pecan orchard and it is impractical because of migration from other trees in pecan trees, to gather up the fallen twigs and burn them in order to kill the larvæ, they may be effectually dealt with through the use of arsenate of lead.

The German genera and species of the ichneumonid tribe Anomalini, O. Schmiedeknecht (Naturw. Ztsehr. Forst u. Landw., 14 (1916), No. 3-4, pp. 97-116, figs. 4).—A synopsis of the forms of this important tribe (parasites of Lepidoptera) which occur in Germany.

Note on an interesting case of two generations of a parasite reared from the same individual host, P. H. Timberlake (Canad. Ent., 48 (1916), No. 3, pp. 89-91).—The author records the rearing of two generations of the braconid parasite Dinocampus americanus from the convergent lady beetle (Hippodamia convergens). This shows that this parasite does not injure the vital organs of its host.

The European Trichogramminæ, with particular consideration of their practical importance as parasites, M. Wolff (Ztschr. Forst u. Jagdw., 47 (1915), Nos. 8, pp. 474-497; 9, pp. 543-568, figs. 24).—A synopsis of the European forms of this important subfamily of parasites.

A preliminary report on the life economy of Solenopsis molesta, J. W. McColloch and W. P. Hayes (Jour. Econ. Ent., 9 (1916), No. 1, pp. 23-38, pl. 1, fig. 1).—A report of biological and economic studies of the Kafir ant (S. molesta), which in Kansas destroys the seed of Kafir corn, cane, milo maize, and feterita. The most practical control measures in southern Kansas consist in fall plowing and thorough spring harrowing, as well as surface and early planting of the crop.

Spraying versus beekeeping, B. N. Gates (Mass. Bd. Agr., Apiary Insp. Bul. 10A (1916), pp. 22, pls. 2).—This paper reviews the literature and reports instances of losses of bees occasioned by their working upon fruit trees, etc., that were sprayed while in bloom.

Fifth and sixth annual reports of the state inspector of apiaries for the years 1914 and 1915, B. N. GATES (Agr. of Mass., 62 (1914), pp. 407-415, pl. 1; 63 (1915), pp. 111-138, pls. 3; Mass. Bd. Agr., Apiary Insp. Buls. 9 (1915), pp. 11, pl. 1; 10 (1916), pp. 30, pls. 3).—The most recent of these reports, which are along the lines of previous years (E. S. R., 32, p. 556), includes an appendix giving the paper above noted on Spraying v. Beekeeping.

Is the hive a center for distributing fire blight? Is aphid honeydew a medium for spreading blight? H. A. Gossab (Jour. Econ. Ent., 9 (1916), No. 1, pp. 59-64, pls. 2).—The tests here reported "prove conclusively to us that the blight organism, in honey, can remain sufficiently virulent for 47 hours to produce infection, with the extreme time measure of virulency probably not reached. Tests of this kind were made with fresh apple honey and also with well-ripened honey taken from the hive in midsummer and the results were substantially the same. It is evident from these results that the formic acid of honey is not immediately fatal to the blight organism. . . . We believe we have proved that if one bee carries 100,000 bacilli into the hive one day, that on the following one or two days, each of 1,000 bees has the possibility of carrying a considerable fraction of 100 virulent bacilli out to fruit blossoms, because practically all the bees in the hive are at work during the night curing the honey. This would seem to go a long way toward explaining the wholesale infection that occurs in the latter part of the blooming period."

The Pajaroello tick (Ornithodorus coriaceus), W. B. Herms (Jour. Parasitology, 2 (1916), No. 3, pp. 137-142, fig. 1).—Notes are given on the life history and biting habits of this tick, based largely upon observations in California by the author and W. L. Chandler.

This tick has been found to occur in a number of counties of the State, including San Benito, Santa Clara, Stanislaus, Monterey, and Santa Barbara, and probably also Los Angeles and San Diego, thus connecting up with Mexico, which is the original habitat. It is most commonly found among dry leaves beneath live-oak trees, where cattle are accustomed to lie in the shade.

Eggs deposited March 9 hatched March 31, giving an incubation period of 21 days, at an average temperature of 26.3° C. A larva placed on the ear of a rabbit May 2 was recovered fully engorged May 11, and molted 10 days later, on May 21. The second molt, without a second engorgement, took place June 15. The nymph became fully engorged in about 20 minutes, on July 2; the third molt occurring August 12. It again engorged October 11, the fourth molt taking place December 23. After another engorgement on January 16, the fifth molt took place on March 9 and the tick appeared as a sexually mature female. On March 27 the female became fully engorged, copulation took place on April 17, and on June 10 428 eggs were deposited.

The number of molts varied from four to seven. The maximum number of eggs deposited by a tick in one season was 1,158, there being seven separate layings.

Both nymphs and adults readily attached to man, monkey, rabbit, and mouse, and became fully engorged in from 15 to 30 minutes. A sharp pain is felt at the time the bite of the tick takes place and the point of attachment remains highly irritated for several days, during which time a scab forms. An extensive swelling of the affected part may follow its bite.

# FOODS-HUMAN NUTRITION.

Skim milk in human and animal nutrition, L. MALPEAUX (Vie Agr. et Rurale, 6 (1916), No. 23, pp. 401-407, fig. 1).—Data are given regarding the nutritive value of skim milk and its use as food for man, calves, and pigs.

The soy bean as a food material, W. Schieder (Seifensieder Ztg., 42 (1915), No. 22, pp. 471, 472).—Descriptions and analyses are given of a number of different products prepared from the fermented and the unfermented soy bean.

Chemical composition of the fruit of the cheromayer, A. Cutolo (Staz. Sper. Agr. Ital., 48 (1915), No. 12, pp. 889-898).—Data are reported regarding the chemical composition of the pulp, skin, and seeds of this fruit, which somewhat resembles the pear.

Maté tea, O. RAMMSTEDT (Pharm. Zentralhalle, 56 (1915), Nos. 4, pp. 29-34; 47, pp. 708-710).—Analytical data are given regarding a number of commercial samples of maté, which is obtained from the Brazilian herb Erica vulgaris. The active principle of maté is mattein, a substance identical with or closely related to caffein. The composition of maté is also compared with that of tea and coffee.

[Analyses of] extracts and spirits (Maine Sta. Off. Insp. 77 (1916), pp. 21-40).—This publication reports the results of the analysis of a number of samples of extracts of peppermint, wintergreen, vanilla, lemon, etc., together with a statement regarding them by A. M. G. Soule.

[Food and drug inspection and analysis], C. L. CLAY (Bien. Rpt. La. Bd. Health, 1914-15, pp. 63-105, figs. 2).—Analytical data are reported regarding 2,017 samples of water, miscellaneous foods, drugs, and patent medicines. The results of the inspection of dairies are also given.

[Food inspection], A. W. J. MacFadden (Ann. Rpt. Local Govt. Bd. [Gt. Brit.], 44 (1914–15), pp. 18–20).—This is a review of the work of the food inspectors during the year 1914–15. In addition to the routine work it included the inspection of food for the troops, a continuation of the studies of infant foods (E. S. R., 32, p. 661), the inspection of food for exports, and the investigation of several outbreaks of food poisoning.

Food and oil laws of the State of Wyoming (Cheyenne, Wyo.: Office Dairy, Food, and Oil Comr., 1915, pp. 82).—The text of the laws is given, together with rules and regulations adopted by the food commissioner, and the standards of purity for food products.

Hints on inspecting canned foods, W. D. Bigelow (Chem. Engin. and Manfr., 24 (1916), No. 3, pp. 108-110).—Among the factors stated to be of importance in the inspection of canned goods are a knowledge of the raw product and the methods and conditions of manufacture; the external appearance of the can; the odor, flavor, and appearance of the contents of the can on being opened; and the bacteriological examination.

A proposed score card for refrigerators, W. A. Evans (Amer. Jour. Pub. Health, 6 (1916), No. 7, p. 743).—A score card is described which can be used by health departments, food departments, manufacturers, merchants, or housewives. The apparatus required consists of ice scales, a thermometer, a tape line, and a hygrometer. The factors considered are the temperature of the food

chamber, ice economy, humidity, circulation of air, interior finish, drainage, and exterior finish.

The bacillus carrier and the restaurant, A. I. Kendall (Amer. Jour. Pub. Health, 6 (1916), No. 7, pp. 726-729).—This article considers the danger of the contamination of food by the bacillus carrier, and describes the measures taken to prevent such contamination in the restaurant of a department store when it was possible that some of the cooks and waitresses had been exposed to typhoid infection. The measures taken included thorough scrubbing of the hands before starting work and after any absence from the restaurant during the day; the application of the Widal test; and the examination of the urine and the feces.

[Care of the baby], E. F. LADD and ALMA K. Johnson (North Dakota Sta. Spec. Bul., 4 (1916), No. 5, pp. 97-132, figs. 8).—This contains information on the care and feeding of children.

The diet of children after infancy, J. H. M. Knox (Jour. Amer. Med. Assoc., 67 (1916), No. 6, pp. 432-435).—This paper calls attention to such data as are available regarding the food requirements of young and growing children, and gives diet lists suitable for a child from 12 to 18 months and a child from 2 to 4 years of age. The author emphasizes the importance of giving more consideration to the diet of young children.

The new emergency ration [of the U. S. Army] (War Dept. [U. S.] Ann. Rpts., 1915, I, pp. 271, 272).—A brief progress report of the work on the emergency ration conducted by the Office of Home Economics of the U. S. Department of Agriculture.

Report by the departmental committee appointed to inquire into the question of maintaining and if possible increasing the present production of food in Scotland, E. WASON ET AL. (Edinburgh: Govt., 1915, pp. 16).—A number of recommendations are formulated.

Minutes of evidence taken before the departmental committee appointed to inquire into the question of maintaining and if possible increasing the present production of food in Scotland (*Edinburgh: Govt., 1915, pp. 166*).—This publication contains the minutes of the hearings and other evidence upon which the above report was based.

The normal gastric secretion, M. E. Rehfuss (*Proc. Amer. Phil. Soc.*, 55 (1916), No. 6, pp. 461-470).—In this article the author brings together a great deal of information regarding the normal secretion of the gastric juice which has been obtained in a number of experiments by himself and other investigators, notably Hawk, Bergeim, Fowler, Spencer, Clarke, and others. The bulk of the material has been noted from other sources.

The uric acid solvent power of normal urine, H. D. Haskins (Jour. Biol. Chem., 26 (1916), No. 1, pp. 205-215).—The experimental data here reported may be summarized briefly as follows:

"When shaken with uric acid for 20 minutes at 37° C. many urines that are slightly acid and all that are neutral or alkaline take up extra uric acid. The less acid the urine the more uric acid, as a rule, it will dissolve. Dilute urines when considered in proportion to their concentration show much greater solvent power than less dilute urines.

"Some urines dissolve so much uric acid that they come to contain more uric acid than is present in a saturated solution of monosodium urate. In all probability in these cases at least part of the uric acid is in colloidal solution."

Creatin in human muscle, W. Denis (Jour. Biol. Chem., 26 (1916), No. 2, pp. 379-386).—Employing the method of Folin, the author studied the creatin content of samples of muscle obtained at the autopsies of 5 normal individuals and 72 individuals dying from various diseases. Determinations were also made of the creatin in muscles obtained from several autopsies of children.

From the results reported it appears that "the fact that the muscle of children contains much less creatin than that of adults was confirmed." These results apparently confirm the theory concerning the relationship of muscle creatin and urinary creatinin in man offered by other investigators, who have called attention to the low creatinin coefficients in the case of persons in a feeble and wasted condition; as such individuals become convalescent and show an increase in the "muscle tonus" a rise in the creatinin coefficient is noted.

The creatinin and creatin content of the blood of children, B. S. Veeder and M. R. Johnston (Amer. Jour. Diseases Children, 12 (1916), No. 2, pp. 136-144).—This paper reports experimental data regarding the content of creatin, creatinin, and nonprotein nitrogen in the blood of children under normal and clinical conditions. The data are based upon experiments made with 75 children.

Experimental studies on creatin and creatinin.—V, Protein feeding and creatin elimination in pancreatic diabetes, W. C. Rose (Jour. Biol. Chem., 26 (1916), No. 2, pp. 331-338).—The author reports experiments in continuation of earlier work on the influence of diet on the elimination of creatin and creatinin (E. S. R., 26, p. 158).

Experiments with laboratory animals (dogs) showed that protein feeding in the animals after complete extirpation of the pancreas did not lead to the disappearance of creatin from the urine, as was the case with similar feeding in normal fasting animals. In the opinion of the author the behavior of the creatin elimination in phlorizin and pancreatic diabetes offers proof of the dependence of the creatin elimination upon the carbohydrate utilization.

Experimental studies on creatin and creatinin.—VI, Protein feeding and creatin elimination in fasting man, W. C. Rose, F. W. Dimmitt, and P. N. Cheatham (Jour. Biol. Chem., 26 (1916), No. 2, pp. 339-344).—The results are reported of observations upon two normal, healthy young men receiving a diet of eggs after a period of fasting. The following conclusions are drawn:

"Contrary to the generally accepted idea, protein feeding in starving man promptly reduces the creatin output to nil.

"The amount of acetone bodies present in the urine during short fasts (three to four days) is not sufficient to render the creatin-creatinin figures unreliable. Four times the quantities of acetone and diacetic acid eliminated in the present experiments were entirely without effect upon the creatinin readings."

Experimental studies on creatin and creatinin.—VII, The fate of creatin and creatinin when administered to man, W. C. Rose and F. W. DIMMITT (Jour. Biol. Chem., 26 (1916), No. 2, pp. 345-353).—Excessively large doses of creatin and creatinin were fed to individuals in nitrogen balance and the effect observed on urinary composition, particularly with reference to the output of urea. The following conclusions are drawn:

"The ingestion of large doses (20 gm.) of creatin in man leads to a very perceptible increase (0.30 to 0.49 gm.) in the output of creatinin. This increase in urinary creatinin is attributed to a conversion of creatin into its anhydrid, and not to an increase in the output of endogenous creatinin.

"The ingestion of large doses (16 gm.) of creatinin is not followed by the appearance of creatin in the urine. This indicates that the reaction Creatin→Creatinin+Water is probably not a reversible one in the human organism.

"No evidence was obtained indicating a transformation of creatin or creatinin into urea by the body cells. On the contrary, urea is probably not a catabolic product of these substances."

The physiological action of glucal, J. O. Balcar (Jour. Biol. Chem., 26 (1916), No. 1, pp. 163-171).—This investigation was made in view of the fact

that glucal is so closely related to glucose and may possibly be an intermediate stage of glucose metabolism. In addition to studying the chemical characteristics of glucal, experiments were carried out with various laboratory animals which showed that glucal is not toxic, produces no effect on blood pressure or on respiration when injected intravenously in moderate quantities, and is not completely metabolized by the animal body when injected at the rate of 0.9 gm. per kilogram of body weight per hour.

The lipoids ("fat") of the blood in diabetes, W. R. Bloor, E. P. Joslin, and A. A. Hornor (Jour. Biol. Chem., 26 (1916), No. 2, pp. 417-430).—The observations here reported show in part that "in severe diabetes the blood lipoids were all markedly increased, up to 100 per cent or more of the normal values. In mild diabetes the lipoids may be normal. In general, the more severe or long standing the diabetic condition, the more marked was the abnormality in the blood lipoids.

"In spite of the high values, the relations between the lipoids were practically those of normal individuals, indicating that the fat metabolism was essentially normal."

For earlier work, see previous notes (E. S. R., 34, pp. 562, 563).

Pellagra—a critical study, J. Aulde (Med. Rec. [N. 7.], 90 (1916), No. 5, pp. 181-185).—The author advances the theory that the essential factor in the production of pellagra, scurvy, and beri-beri is the mineral deficiency in the protein molecule, and that calcium depreciation is responsible for pellagra.

Preliminary observations on metabolism in pellagra, A. Hunter, M. H. Givens, and R. C. Lewis (*Pub. Health Serv. U. S. Hyy. Lab. Bul. 102* (1916), pp. 39-67).—Data are given regarding the amount of indican excreted and the nitrogen balances in the case of a number of inmates of the pellagra hospital at Spartanburg, South Carolina.

Pellagra.—The value of the dietary treatment of the disease, J. R. Ridlon (Pub. Health Rpts. [U. S.], 31 (1916), No. 30, pp. 1979-1999).—This report is based on observations upon 58 pellagra patients in the U. S. Marine Hospital at Savannah, Ga. The patients were given a diet relatively rich in animal and leguminous protein component and relatively poor in nonleguminous-vegetable component. It is concluded from these cases that the dietectic treatment of pellagra is of paramount importance, and "that in this series success has followed the use of a diet in which the animal and leguminous-protein component has been relatively increased and the nonleguminous-vegetable component relatively decreased."

As a part of the histories of the pellagra patients an attempt was made to ascertain the diet consumed during the three months previous to the appearance of the disease. The data collected from 35 patients are reported in this article. "A study of these diet histories shows that the vegetable and fat components were notably conspicuous and that the animal protein foods were relatively inconspicuous."

The energy metabolism of a cretin, F. B. Talbor (Amer. Jour. Diseases Children, 12 (1916), No. 2, pp. 145-148, fig. 1).—The heat production of a cretin, 3 years 8 months old, was determined by the calorimeter to be 898 calories per square meter of body surface, or 40.5 calories per kilogram body weight.

## ANIMAL PRODUCTION.

Meat situation in the United States, I-IV (U. S. Dept. Agr. Rpts. 109 (1916), pp. 307, pl. 1, figs. 31; 110 (1916), pp. 100, pls. 6; 111 (1916), pp. 64, pls. 5, figs. 2; 112 (1916), pp. 27).—This portion of the report is treated in four parts.

I. Statistics of live stock, meat production and consumption, prices, and international trade for many countries, G. K. Holmes.—This treats of the number of meat animals in the United States and other countries, meat exports and imports, production and consumption, losses of meat animals, prices, meat-producing conditions in other countries, and conditions and problems in the United States. Under this last heading are treated local origin of cattle for slaughter and feeding, age of beef cattle, yearly marketings of meat animals, yearly slaughterings at principal places, increase of retail over wholesale price, and 1-year tenancies.

II. Live-stock production in the eleven far western range States. Based on reports from stockmen and county correspondents, W. C. Barnes and J. T. Jardine.—The data contained in this report are based upon studies made in the summer of 1914 of conditions in Arizon, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.

The studies show that in these 11 States there was an estimated reduction of 859,120 cattle and 4,537,578 sheep in 1914, as compared with 1910. Considering four sheep as the equivalent of one cow, this means a reduction of approximately 13 per cent in live stock (cattle and sheep). The entry and settlement of approximately 85,500,000 acres of lands in these States since 1909 has resulted in a decrease of approximately 16 per cent in live-stock production since 1910 due to the breaking up of ranges formerly used as breeding grounds for cattle and sheep. High prices and general farm development in the range region have resulted in increased winter feeding of range live stock, thereby reducing the amount of range necessary per animal, and consequently in part offsetting the decrease due to settlement. "Uncertainty as to future conditions, difficulty of securing money for purchase of breeding stock, increase in value of land and dairy products, improvement in grade and weight of animals at the expense of numbers, drought and severe winters, and range deterioration have had some effect in bringing about decreases in numbers during a part of the period 1910-1914, but, considering this period as a whole, these factors had only a small influence in the aggregate."

As regards the possibilities of increased production in the future the investigations indicate that there will probably be an increase of 15 per cent in the next ten years, from 1915 to 1924, inclusive, because settlers on approximately 100,000,000 acres of range lands settled since 1905 will turn to raising live stock; the carrying capacity of summer range within National Forests will increase probably 15 per cent, and winter feeding adjacent to National Forest ranges will probably increase accordingly; and better management of stock, both on farms and on the range, will result in greater economy in the use of forage and, consequently, will increase the number of stock produced with a given amount of forage.

From a study of the cost of production, it is concluded that for sections of the West where winter feeding is practiced the man who contemplates substituting live stock for other forms of agriculture should figure on a cost of approximately \$30 for the production of a good yearling, and \$45 for the production of a good long 2-year-old; this cost to include labor, market value of feeds, taxes, loss, bull service, and any depreciation of breeding stock. In sections of these same States where only a part of the stock is fed in winter the cost of producing a yearling may be set at approximately \$25, and of a 2-year-old at \$35. In the range sections of the Southwest the cost of producing a yearling may be set at from \$15 to \$19, varying greatly with the number of calves per 100 cows, and the cost of producing a long 2-year-old at approximately from \$20 to \$25. The average weight given for a 2-year-old steer in the feeding sections is 960 lbs. At \$45 as the cost of production, the cost per pound is about

4.6 cts. For Arizona and New Mexico the average weight of a 2-year-old steer is given as 775 lbs. At \$25 for production the cost per pound is a little over 3.2 cts. For the Southwest, hazard due to the exceptional loss in time of prolonged drought is not fully covered in the above costs.

On the basis of the report of the U. S. Tariff Board of 1911 together with modifications to bring the figures down to 1914, it is estimated that the cost of producing a lamb in California is \$1.55, in Arizona, Colorado, and New Mexico, \$1.71, and in Idaho, Montana, Nevada, Oregon, Utah, Washington, and Wyoming, \$1.82. These figures cover loss and depreciation, provide for interest on capital invested in land, improvements, and equipment, and include wool at market price.

A brief discussion is given of conditions in each State included in the investigations.

III. Methods and cost of growing beef cattle in the corn-belt States. J. S. Cetton, M. O. Cooper, W. F. Ward, and S. H. Ray.—The object of this study was to determine as accurately as possible the cost of producing beef animals or corn-belt fartas. In order to get significant figures, 506 records were obtained from farms chosen at rendom in the States of Italiana, Illinois, Minnesota, Iowa, Missouri, South Dakota, Nebraska, and Kansas. An effort was made to get at least 20 records in a locality. The farms visited in the various States ranged in size from an average of 294 acres in Indiana and Illinois to 566 in Kansas. The value per acre ranged from \$50 in Indiana to \$175 in Iowa, Records were procured on 14,634 cows and 621 bulls, and on 12,591 calves produced from them, of which 2,023 were fattened for baby beef.

The records were arranged in six groups, classified as (1) beef (farms where all the cows are kept strictly for beef, but not including farms producing baby beef: (2) baby beef (farms on which the breeding herds are maintained for the production of high-grade calves which are fattened on the same farm and sold at from 12 to 18 months of are); (3) dual purpose (farms on which all of the cows are milked, and either cream or butter sold, the calves being weaned at birth and raised on skim milk); (4) mixed (farms on which the practice is to milk the best cows, their calves being weaned at birth and fed skim milk, the calves from the other cows being allowed to run with their dams as in the beef group): (5) partially milked (farms on which the calves are not weaned, but on which a part of the milk is drawn from the cow, the calf taking the remainder); and (6) double nursing (farms where some of the cows are milked and their calves given to other cows, the latter raising two calves each). The results are considered representative of the present-day operations of the cornbelt stock farm. The following table shows for the six groups the various factors that make up the cost of producing a yearling:

Summary of the various factors that make up the cost of producing a yearling.

Item.	Beef.	Baby beef. 2	Dual purpose.	Mixed.	Partially milked.	Double nursing.
Number of farms. A ename number of cowe per farm. Cost of mountaining the breeding hard:	230 31.50	86 34, 56	110 12.75	102 23. 47	65 14. 29	17. 32
Gross cost of maintaining a cow. Credita shoet blance at Net cost of maintaining a cow. Net cost of maintaining a built.	\$35, 12	\$36, 77	\$55.14	\$43.95	\$42.75	\$46, 50
	\$4, 79	\$5, 39	\$49.07	\$24.72	\$21.43	\$33, 26
	\$36, 23	\$31, 38	\$6.07	\$19.23	\$21.32	\$13, 24
	\$42, 27	\$53, 26	\$37.51	\$46.79	\$34.14	\$40, 53
Call crops Percentage of cowe raising calves to weaning time. Nominer of calves per buil	84.90	90.70	83.90	87. 50	90.10	92.10
	20.90	25.30	16.70	18. 50	12.60	15.00

c The statement for the baby-beef group gives figures on the calves until they are marketed at approximately 15 months of age.

Summary of the various factors that make up the cost of products a yearline—Continued.

•A change in the number of farms on which the tab library of the post of producing yearlings is based courses the figures on bast of ball at wearing time (or change in this part of the table).

I Italie figures here call attention to the last that the body-beef animal is carried somewhat beyond the yearing stage.

"The data obtained indicate that the keeping of cattle for beef purposes alone is adapted to the more extensive types of farming, while the keeping of cattle primarily for beef purposes, but where an income is also obtained from milk products, is better adapted to the more intensive types of farming.

"The averages brought out in this investigation would seem to indicate that profits obtained from the raising of ealves on corn-belt farms are very small. However, the following facts must be taken into consideration: (1) Good returns have been obtained for a large quantity of roughage which had it not been utilized by live stock, would have been waste: (2) a home market has been provided for salable crops: (3) on many farms a large access suitable to pasture only has been utilized: (4) profitable employment is provided for a season of the year when labor otherwise might be take: (3) a return is obtained for capital invested in equipment which, in many instances, were it not utilized by live stock, would return to thing; and (6) when the farmer merely breaks even he has at least made 6 per cent interest on the money be has invested in the cattle business. When all of these factors are taken into consideration, even though there appears to be little or no profit, it is believed that in most cases the farm income is greater because of cattle having been kept on the farm."

IV. Utilization and efficiency of available American feedstuffs. W. F. Ward and S. H. Ray.—In this study the total loss to farmers from the waste of corn fooder and straw is estimated at about \$102,860,000 each year.

In 1914 about 120,000,000 tons of straw was produced in the United States. Of this, 55 per cent was fed to live stock, while 15 per cent was hurned 8 per cent sold, and 22 per cent plowed under or otherwise disposed of. It is suggested that greater publicity concerning the value of straw, its use as a filler in commercial feeds, and in various manufactures, might aid somewhat in preventing its waste.

Corn stover produced in the United States is estimated at 245.253.001 tons, of which \$1.5 per cent was fed to cattle and other stock. No data were attained as to the percentage wasted in feeding, but is estimated as at least \$5 per cent. This waste can be checked through the use of better methods for feeding fodder and stever, and it can be almost entirely stopped through the use of silos. Of the total amount of stover produced \$7 per cent was burned, 10.2

per cent plowed under, and the rest sold or disposed of in other ways. Emphasis is put on the advantage of using as large an amount as possible of these materials for silage, only 8.1 per cent of the corn acreage now being used in this way.

To feed the large quantities of straw and stover now wasted would necessitate the feeding of large quantities of concentrated feeds which are now disposed of in a less economical manner. For instance, more than 810,000 tons of cotton-seed meal was used in six southern States in 1914 for fertilizer. If this had been fed to live stock and the manure used for fertilizer the value of the meal would have been increased from 50 to 85 per cent. This is true of all the oil meals used for both fertilizer and feeding purposes. The food value of these concentrated protein materials can be further increased through the more extensive use of silage.

A nation-wide campaign to teach the value and use of food-unit values for all the more common feeding stuffs is advocated.

More experimental study of spineless cactus as a feeding stuff is suggested. Common sugar cane and Japanese sugar cane are regarded as very promising forage crops for the extreme South, while the utilization of the by-products of sugar cane, such as cane tops, bagasse, and blackstrap molasses, may afford large savings in the cane-growing section. Feterita and Sudan grass are deemed promising for the semiarid West. Sudan grass as an important hay crop in other sections of the country, and teosinte in the extreme South.

Silage crops are deemed more economical than roots and serve almost the same purpose. The animal by-products, such as tankage, fish meal, etc., are excellent feeds for hogs, but are little used for cattle. Dried brewers' grains and distillers' by-products are in general use and are generally fed with care. Improvements could probably be made in the method of feeding the slop by the use of other concentrated feeds and some dry roughage. Canning factory refuse could be increased in value by storing in silos rather than in huge piles in the open. Beet pulp is usually handled in an economical manner and comparatively little of it is wasted.

Investigation in animal nutrition: Beef production, T. L. HAECKER (Minnesota Sta. Bul. 155 (1916), pp. 3-31).—During the winter of 1907-8 a series of experiments was inaugurated with beef-bred calves to determine their composition by making a complete chemical analysis of a fairly representative one at each period of 100 lbs. gain in weight, and also to keep a complete record of all food consumed by each animal and the dry matter and digestible nutrients required for production to the various stages of growth. The records of five groups are given and commented upon.

The calves received from 8 to 10 lbs. of whole milk per day for two or three weeks, according to the judgment of the feeder, and then a gradual change was made to separator skim milk. The roughage fed was choice upland prairie hay and corn silage. The concentrates were farm grains and their standard by-products, such as bran, flour middlings, and oil meal. All the steers were kept in the barn during their lifetime, except that half the steers from three groups were turned to pasture when they were one year old. During the first year they were all kept in small portable stalls. During the second year those that were retained in the barn on continuous stall-feeding had the freedom of a runway in the barn and were confined in portable stanchions only while they were eating their rations. Each steer always received as much hay and silage as he would eat, and the amount of grain required was determined by the feeder. The following table presents data based on the average of all the

steers in the five groups, showing the growth during the various stages and the feed requirements found necessary to convert a calf into a 1,200-lb. steer, ready for market, in approximately two years:

Average weights and gains per steer, feed consumed and total cost of feed consumed per steer, and cost per pound of gain.

Data on two of the groups turned out to pasture as yearlings are given. Their weight as yearlings averaged 601.9 lbs. The steers were returned at the proper time, weighing an average of 707.6 lbs., and after a week's preliminary feeding were started on a feeding experiment. They were kept in an open runway, but twice a day were confined to stanchions while they were taking their morning and evening rations. The following table shows the average gains made and feed consumed:

Summary of pasture lots.

Period.	Average weight per steer.	Average gain per steer.	Grain consumed per steer.	Hay consumed per steer.	Silage consumed per steer.	Grain consumed daily per steer.	Average daily gain per steer.	Grain consumed per pound gain.

The average feed cost per steer for the first year was \$30.48 and for the second year after returning from pasture, \$35.84.

The difference in cost of production between the steers on continuous stallfeeding and those turned to pasture the second year affords data on the benefits

64968°-16-6

derived from pasture. The pastured steers of one group were in pasture 140 days and gained an average of 125 lbs. per head. During the time they were on stall feed the average cost was \$61.70. They sold for 7.75 cts. per pound, while the lot on continuous stall-feeding cost \$81.07 per head and sold for 8.25 cts. per pound. The pastured steers brought \$23.16 net per head, and the stall-fed steers \$9.38, so that the pasture saved 68.9 cts. per week on feed cost of production. The steers of the other group were in pasture 153 days and gained an average of 44.4 lbs. per head. The stall-fed steers brought an average of \$19.36 net per head, and the pastured steers \$26.26. Even under the small gain made they saved 31.4 cts. per week per head on feed cost of production.

[Animal husbandry] (Nebraska Sta. Rpt. 1915, pp. X, XI, XV, XVI).—In an experiment in pig feeding, carried on to determine the relative values of tankage and alfalfa hay in supplying protein to a ration in which ear corn and shelled corn were used, the results showed that the cheapest gains were made on a ration of ear corn and alfalfa hay. The addition of tankage to a ration of shelled corn and alfalfa increased the rate of gain and lowered the cost of gain when compared with shelled corn and alfalfa hay. However, this cost was higher than the cost of gains made with ear corn and alfalfa hay.

Seven lots of lambs were fed 90 days as follows: Lot 1, corn and oil meal on grass pasture; lot 3, corn, alfalfa hay, and silage; lot 4, corn, alfalfa hay, rape pasture, and turnips; and lot 6, corn and alfalfa hay in a dry lot; lots 2, 5, and 7 running in a cornfield and receiving in addition cotton-seed cake and alfalfa hay, alfalfa hay, and oil meal and alfalfa hay, respectively, after frost. The gains made varied from 0.18 to 0.27 lb. per day. The net profits for the lots 1 to 7 were \$1.22 and 97, 91, 87, 68, 68, and 66 cts., respectively. In this experiment the lambs upon grass pasture with corn and oil meal made materially better gains than any other lot. The lot running in a cornfield receiving alfalfa hay after frost did not make as favorable gains as could normally be expected, owing to disturbances while the feeding experiment was in progress.

Experiments in pork production at the North Platte substation indicate that stewing or cooking alfalfa has increased the rate of gain slightly and slightly decreased the food eaten per pound of gain. However, the cost of stewing the alfalfa probably was greater than the advantages gained. The proportions of corn, tankage, and alfalfa hay eaten from self-feeders by fall shotes during the winter, where skim milk formed a part of the ration, were corn 85.1, alfalfa hay 8.1, and tankage 6.8. The food consumed per pound of gain was corn 2.915 lbs., alfalfa hay 0.278, tankage 0.235, and skim milk 2.58 lbs.

Three lots of lambs were fed during a winter as follows: Lot 1, corn and alfalfa; lot 2, corn, alfalfa, and cotton-seed cake; and lot 3, corn, corn silage, and alfalfa. The lot fed silage made a trifle larger gain, about 2.5 lbs. per head per week. The lambs fed cotton-seed cake gave a little more profit than those fed either of the other two rations, but probably not sufficiently greater to warrant the feeding of cotton-seed cake when the price is much above \$30 per ton. Silage at \$4 per ton was so expensive that the ration containing it produced less profit than either of the other two rations. The cost per pound of gain on a ration of corn and alfalfa hay was 5.7 cts.

Hogging down soy beans and cowpeas, E. S. Good and M. J. Smith (Kentucky Sta. Bul. 201 (1916), pp. 139-149, figs. 2).—Three lots of 90-lb. pigs were fed as follows: Lot 1, hogging down soy beans plus corn meal equal to 2 per cent of their body weight; lot 2, hogging down soy beans without corn; and lot 3, hogging down cowpeas and corn meal equal to 2 per cent of their body weight. The average daily gains made were 1.3, 0.261, and 0.303 lbs. per pig, and the cost per pound of gain, including cost of seed sown, plowing and cultivation, rent of land, labor involved in feeding, and corn consumed, was

4.54, 12.52, and 21.73 cts., for the respective lots. The total fertilizing value of the respective lots was estimated to be \$17.68, \$12.93, and \$3.61.

The results indicate that it is not profitable to hog down soy beans (grain) unless a supplementary feed is given, for only 110 lbs. of pork were produced per acre with such a procedure, which did not pay for the seed sown, cost of cultivation, and rent of land.

It was found highly profitable to hog down soy beans when a supplementary feed, such as corn, was given, for the lot of hogs receiving 2 per cent of its weight in corn meal daily produced 825 lbs. of pork per acre at a cost of 4.54 cts. per pound gain. Valuing pork at 7 cts. per pound, the net value of pork produced by this acre of soy beans was \$20.32, which, with \$17.68 for the fertility left on this acre of ground, would make a total of \$38. It was not found profitable to hog down cowpeas, even if supplemented with corn meal.

The acre of soy beans hogged off with a supplementary feed of corn produced feed for 10 hogs for 21 days and for 20 hogs for an additional 21 days. The acre of soy beans with no corn produced feed for 10 hogs for 21 days and for 15 hogs for an additional 14 days. The acre of cowpeas hogged off with a supplementary feed of corn meal given the hogs furnished feed for 15 hogs for 22 days.

Cooperative live-stock shipping associations in Minnesota, E. D. Durand (Minnesota Sta. Bul. 156 (1916), pp. 5-29, figs. 3).—This bulletin treats of the general character of the cooperative live-stock shipping-association movement, the number and location of such associations in Minnesota, and their distribution and volume of business, and gives suggestions for conducting the business and method of organization, including a suggested constitution and by-laws. The text of the Minnesota laws governing cooperative associations is appended.

Stallion enrollment.—V, The stallion enrollment law and the farmer, H. E. McCarney (Indiana Sta. Circ. 52 (1916), pp. 16, fig. 1).—An explanation of the Indiana stallion-enrollment law and the benefits of the law. It is shown that during the two years in which the law has been in operation there has been a decided increase in pure-bred stallions and jacks and a decrease in grades and scrubs.

Announcement regarding the egg-laying contest, J. J. Hooper and R. H. Wilkins (Kentucky Sta. Circ. 12 (1916), pp. 27-39, figs. 5).—This is an announcement of an egg-laying contest to be held at the Kentucky Experiment Station, beginning November 1, 1916, together with the rules and regulations governing the same.

# DAIRY FARMING-DAIRYING.

[Dairying] (Nebraska Sta. Rpt. 1915, pp. XI-XIII).—Three years' experimental work to test the relative values of alfalfa hay and corn silage in milk production indicates that with the quality of silage and alfalfa hay which has been fed in these experiments, when corn silage is worth \$3.50 per ton to produce milk, alfalfa hay is worth \$8 per ton. This would indicate that where alfalfa hay is cheap and abundant the use of silage will not lessen the cost of milk production unless it can be produced at a lower cost than was charged for it in these experiments.

Corn silage has given more favorable results than alfalfa silage, due largely to the improper fermentation of alfalfa silage, which affected its palatability. Recent experiments have shown that a mixture of one-half green sorghum with one-half green alfalfa makes a good quality of silage, but the feeding value of this mixture has not been compared with corn silage.

A plan for a soiling crop on the basis of ten cows and adapted to Nebraska conditions is given. Experiments indicate that milk fat produced from soiling crops will be more expensive than where produced upon silage or pasture. Among the soiling crops used alfalfa produced milk and milk fat at the lowest cost.

The feeding of dairy cows, H. Rabild, H. P. Davis, and W. K. Brainerd (U. S. Dept. Agr., Farmers' Bul. 743 (1916), pp. 23).—This discusses the factors involved in the economical selection of feeds and methods of feeding, including a discussion of various feeding stuffs and suggested rations.

Cost of milk and fat on pasture and in stable (Ann. Rpt. Ontario Agr. Col. and Expt. Farm., 41 (1915), p. 31).—During the months of June, July, August, and September 32 cows were pastured and 15 cows were fed in the stable on rations identical with those used in the winter. The results were that group 1 produced milk at an average of 45.1 cts. per 100 lbs. and butter fat at 11 cts. per pound, and group 2, milk at 86 cts. per 100 lbs. and butter fat at 22 cts, per pound.

Fourth report on the cost of food in the production of milk in the counties of Kent and Surrey, G. H. Garrad (Southeast. Agr. Col. Wye, Rpt. Cost Food Prod. Milk 4 (1915), pp. 95).—This is a continuation of work previously noted (E. S. R., 33, p. 276). Data on the cost of feed in the production of milk for the period from May 1, 1914, to May 1, 1915, and a brief summary of the results of the past three years' work are given.

ft appears that the more milk a cow gives the cheaper becomes the cost of feed per gallon, and the most economical herds are those that yield well on a normal ration. There was a difference of about 5.5 cts. per gallon (nearly 12.5 cts. per day) between the cost of feeding in the six summer months (May 1 to October 31) and the six winter months (November 1 to April 30), the figures being 5.84 cts. per gallon in the summer and 11.32 cts. in the winter. The effect of a dry summer is felt not merely in increasing the cost of production of summer milk, but also in increasing the cost of the winter milk, because the natural result of a dry summer is a short crop, i. e., an expensive crop, of roots and fodder.

In every year the cost of feeding, per gallon, has been half as much again on the most expensive farm as on the cheapest farm. The 16 cheapest herds (7.08 cts. per gallon) cost 16.28 cts. per cow per day for feed and averaged 2.3 gal. of milk. The 16 most expensive herds (10.06 cts. per gallon) cost 21.82 cts. per cow per day and averaged 2.17 gal. of milk.

Cost of food in the production of milk, C. Crowther and A. G. Ruston (Univ. Lecds and Yorkshire Council Agr. Ed. [Pamphlet] 88 (1913), pp. 32; 91 (1914), pp. 40; 98 (1915), pp. 37, pls. 2).—In these reports data are given on the production of milk in ten herds under study, the value of the milk, the feed consumed, the cost of feeding, and the milk-fat percentage. See also a previous note (E. S. R., 29, p. 278).

Announcement of the California state dairy cow competition, 1916-1918, F. W. Woll (California Sta. Circ. 153 (1916), pp. 8).—An announcement of and regulations governing a dairy-cow competition to be held at the College of Agriculture of the University of California are given.

The bacteria of milk freshly drawn from normal udders, ALICE C. EVANS (Jour. Infect. Diseases, 18 (1916), No. 5, pp. 437-476).—This study included 192 samples of milk from 161 cows of five different dairies in two widely distant sections of the country. No consideration was given to those types of bacteria which occurred in the udder in small numbers. All the cultures which were studied in detail and included in this report represent bacteria which were multiplying in the udder and were found in the milk in considerable numbers.

In 32 samples, bacteria were not multiplying in numbers worth considering. Three types of bacteria were found commonly present in milk from all five dairies; they were streptococci, staphylococci, and bacilli. The ordinary milk-souring organism, Streptococcus lacticus, was not found in any of the samples of milk. It does not appear to localize and multiply in the udder. Long-chained streptococci which failed to give the reduction of litmus in milk cultures characteristic for S. lacticus were isolated from 29 samples. The highest number found per cubic centimeter was 264,000. Micrococci were found in 113 samples, the highest number found per cubic centimeter being 80,000.

The majority of the micrococci were shown to belong to one group, which agrees in characteristics with the pyogenic staphylococci. The majority of cultures of this type were nonvirulent, but some cultures were virulent, and two cultures possessed such a high degree of virulence that inoculated rabbits died in about 16 hours. Three other types of micrococci from the udder gave reactions which differed from those of the pyogenic staphylococci sufficiently to separate them into distinct groups. One of these groups is described, but no name is suggested for it because of the small number of cultures studied. Another group was identified with *Micrococcus luteus*, according to Winslow's classification. The third group was characterized by the rapid and complete peptonization of milk, and the name *M. cascolyticus* is suggested for this group.

Peculiar strains of the types of bacteria commonly present in freshly drawn milk were sometimes found localized in the udders of several cows of one dairy. A few cases were found of peculiar species, unlike any of the other udder organisms, localized in this same way.

The bacilli commonly present in milk from all five dairies were shown to be related to *Bacillus abortus*. Three varieties of this type were distinguished. The variety occurring most frequently was designated *B. abortus*, variety *lipolyticus*, because it decomposes milk fat. In its cultural characteristics this variety agrees closely with Bang's original description of *B. abortus*. Cultures of this variety were shown to be capable of imparting undesirable flavors and odors to cream kept under conditions to which cream is frequently subjected. Two other varieties of *B. abortus* type differed considerably from the *lipolyticus* variety, but resembled the cultures isolated from pathogenic sources and studied for comparison. Cultures of *B. abortus* type were isolated from 45 of the 192 samples studied. The highest number of these bacilli found per cubic centimeter was 50,000.

The author concludes that "there is a definite udder flora comprising bacteria which belong to parasitic types. It is not surprising that the majority of udder bacteria should be of the same type as those common on the skin and mucous membrane of man and animals. The majority of the staphylococci on the skin are of the nonvirulent variety, which fails to produce pigment and fails to ferment mannite. But pathogenic varieties also are found on the skin, where they ordinarily cause no trouble. Similarly, the majority of the staphylococci of the udder are nonvirulent, but varieties which are capable of causing death when inoculated into experimental animals occasionally establish themselves in healthy udders. Whatever the variety may be, conditions in the udder are favorable to multiplication, and frequently large numbers are eliminated in the milk.

"The pathogenic properties of the streptococci and bacilli common in milk when it leaves the udder are not discussed in this paper, but they also are parasitic in their nature.

"When a bacterial culture is tested for its pathogenic properties the body tissues and fluids are exposed directly to the toxins of the culture in question. When organisms enter into the digestive tract with the food the circumstances are different, for the body tissues and fluids are protected by the mucous membranes against the ravages of the bacteria that enter with the food. Therefore it can not be assumed that bacteria which are pathogenic to inoculated laboratory animals would be injurious to human beings when present in the milk consumed. It is a subject worthy of investigation. But since the bacteria of the udder are parasitic in their nature, and since pathogenic varieties are sometimes eliminated in considerable numbers from healthy udders, the data here reported add evidence to the growing conviction that all milk is safer for consumption after it has been pasteurized."

Studies on the formation of gas in milk, B. W. Hammer (Iowa Sta. Research Bul. 27 (1916), pp. 3-16, figs. 3).—Gas forming organisms were isolated from several cases of gassy curds and their action on milk both alone and in combination with Bacterium lactis acidi was studied.

"The curds secured with the gas formers alone did not resemble the original curd, since but a small amount of gas was held in the curd, while double inoculations gave extremely gassy curds. It is probable that the gassy curds occur with the double inoculations, because a firm curd which will retain the gas results from the acid produced by B. lactis acidi while the gas formation is still in progress. On continued transferring the gas formers lost their ability to produce extremely gassy curds when grown in combination with B. lactis acidi, and this was accompanied by a decreased acid production in inoculated milk held at 37° C. for one week. It seems likely that the decreased acid tolerance is responsible for the failure to produce extremely gassy curds. Other cultures of gas formers grown in combination with B. lactis acidi failed to produce extremely gassy curds, probably because of their failure to grow in the presence of acid. Cultures of B. lactis acidi from different sources seemed to be equally effective in the production of gassy curds when grown with the gas formers isolated.

"B. lactis acidi influenced the total amount of gas produced by the gas former, sometimes increasing it and sometimes decreasing it at 37°, and always decreasing it at room temperature. B. lactis acidi influenced the type of curd formed very materially because of the part it played in causing a retention of the gas.

"The gas-forming organisms from the four cases described were not all the same. B. communior and B. crogenes were the two types encountered."

Comparison of the bacterial count of milk with the sediment or dirt test, H. C. CAMPBELL (U. S. Dept. Agr. Bul. 361 (1916), pp. 6, pl. 1).—The author gives results of an experiment to determine whether the sediment or dirt test can be wholly relied upon as a means of detecting insanitary milk at milk receiving stations. In the experiment the Gerber, the Wizzard, and the Lorenz (E. S. R., 23, p. 180) apparatus were used. Pint samples of milk were collected on the railroad station platform from the milk cans as they arrived from various farmers. After preparing plates, sediment tests were made and the disks were compared with the bacterial counts.

Comparing the bacterial count with the Gerber sediment test with unfiltered market milk, it was found that "some samples had a high bacterial count, yet tested 'good' or 'fair' with the sediment test, while others which had a low bacterial count tested 'medium' or 'bad.'" With the Wizzard sediment test, one sample classed as "good" by the sediment test contained 4,102,000 bacteria per cubic centimeter, while another classed as "bad" contained only 243,000 bacteria per cubic centimeter. With the Lorenz sediment test one sample with a bacterial count of 768,000 tested "fair" by the sediment test, and one with a count of 7,200 bacteria per cubic centimeter tested "bad."

In comparisons with filtered milk 10 samples out of 20 filtered through 4-ply cheesecloth varied in bacterial count from 24,000 to 639,000 per cubic centimeter. Ten average samples out of 20 filtered through one ply of Canton flannel varied in bacterial count from 18,000 to 316,000 per cubic centimeter. Ten average samples out of 20 filtered through 1-ply ordinary absorbent cotton, covered above and below with 1-ply cheesecloth, varied in bacterial count from 31,400 to 760,000 per cubic centimeter. Every sample of filtered milk was classed as good by the Lorenz sediment test.

It is concluded that the result of a sediment test is no criterion as to the kind or number of bacteria contained in the milk. The various sediment tests, while applicable in roughly estimating the quantity of sediment in unstrained milk, can not be used as the sole means of determining the hygienic conditions under which the milk was produced. Sediment testers are deemed of little value in estimating the degree of contamination in milk strained through the substances mentioned. The Lorenz apparatus is considered the most convenient and practical for demonstrating dirt in milk.

The grading of milk, E. Kelly (Hoard's Dairyman, 52 (1916), No. 1, pp. 1, 6, figs. 3).—A discussion of the history and development of the grading of milk, reasons for grading, and systems of grading.

Sanitary condition of dairies (U. S. House Representatives, 64. Cong., 1. Sess., Hearings before Committee on Rules on House Resolution 137, 1916, pp. 101).—This reports hearings before a House committee as to the sanitary condition of dairies in the United States.

A new pasteurizing apparatus for bottled milk, Weigmann, A. Wolff, M. Trensch, and M. Steffen (*Milchw. Zentbl.*, 44 (1915), Nos. 13, pp. 193-202, figs. 2; 14, pp. 209-217).—An apparatus for the pasteurizing of bottled milk, based on the "holder" method is described, together with data on its efficiency in bacterial destruction.

The biorizator, Orla-Jensen (Milchw. Zentbl., 44 (1915), No. 18, pp. 273-277, fig. 1).—The biorizator method and apparatus for pasteurizing milk is described and data given showing its efficiency in reducing the bacterial content without detriment to the quality of the milk.

Biorized milk, K. E. F. Schmitz (Milchw. Zentbl., 44 (1915), No. 16, pp. 241-245, figs. 3).—A discussion of the biorizator and its efficiency in bacterial destruction.

Result of the Lobeck method of milk sterilization (biorization), K. E. F. Schmitz (Ztschr. Hyg. u. Infektionskrank., 80 (1915), No. 2, pp. 233-260, figs. 5).—Experiments with the Lobeck biorizator indicated that it is an effective method of sterilizing milk without impairing the quality, taste, or nutritive value. It was effective in destroying tubercle bacilli.

A simple steam sterilizer for farm dairy utensils, S. H. AYERS and G. B. TAYLOR (U. S. Dept. Agr., Farmers' Bul. 748 (1916), pp. 11, figs. 8).—A simple and inexpensive yet efficient steam sterilizer is described which can be provided at a cost of from \$5 to \$10. It is believed that the sterilizer described is cheap enough to justify its use on any farm from which milk or cream is sold. It is designed to be of greatest use to those who have one, two, or three 10-gal. or smaller cans with a similar number of pails and a strainer cloth, but can be used with a larger number of cans.

When properly operated this sterilizer destroys practically all the bacteria in the utensils, including all disease germs which may be present. It will accomplish the same results as any sterilizer in which steam not under pressure is used. Experiments with this sterilizer show that the 5-minute steaming is, for practical purposes, as good as the 15- to 30-minute steaming usually recommended.

Dry milk or cream powder and a process for its manufacture, S. A. Vasey and U. A. Cleeve (English Patents, 2772 (1915); 7766 (1915); abs. in Jour. Soc. Chem. Indus., 35 (1916), No. 11, pp. 649, 650).—"The particles of a milk or cream powder are coated with a layer of an odorless, liquid hydrocarbon which is nonvolatile at ordinary temperature (e. g., Paraffinum liquidum, B. P.); the product will keep unaltered for a considerable period. Such a powder is produced by projecting milk powder by means of an air blast into an atomized spray of the hydrocarbon, or by mixing the milk, or partially evaporated milk, with the hydrocarbon and then drying the mixture. The finished product should contain not more than 5 per cent of its weight of the hydrocarbon."

#### VETERINARY MEDICINE.

The third and fourth reports of the director of veterinary research, A. Theiler (*Rpts. Dir. Vet. Research, Union So. Africa, 3-4 (1915), pp. 632, figs. 154*).—These reports consist of 17 papers by various authors as follows:

Contribution to the Study of Deficiency Disease, With Special Reference to the Lamziekte Problem in South Africa, A. Theiler, H. H. Green, and P. R. Viljoen (pp. 9-68); Sheep Scab.—Observations on the Life History of Psoroptes communis var. ovis, and Some Points Connected with the Epizootiology of the Disease in South Africa, by A. W. Shilston (pp. 71-98); Experiments and Observations Carried Out with P. communis at Onderstepoort, by G. A. H. Bedford (pp. 101-111); The Sulphur Sheep Dips, by H. H. Green (pp. 115-161); Report upon the Dipping Trials Carried Out with the Different Proprietary and Homemade Sheep Dips in South Africa, by G. A. H. Bedford (pp. 165-172); Upon the Composition and Analysis of Polysulphid Solutions (pp. 175-195) and Arsenical Dip Tester (pp. 199-214), both by H. H. Green; Infectious or Pernicious Anemia of Equines in South Africa, by A. Theiler and D. Kehoe (pp. 217-289); Investigations Into the Life History of the Wireworm in Ostriches, by A. Theiler and W. Robertson (pp. 293-345); The Anatomy and Life History of the Hamonchus contortus, by F. Veglia (pp. 349-500); Some Observations in Connection with the Immunization of Cattle Against South African Redwater and Genuine Gall Sickness (Anaplasmosis), by J. Walker (pp. 503-526); The Cultivation of Anaplasma marginale in vitro, by F. Veglia (pp. 529-532); Aspergillosis in the Ostrich Chick (pp. 535-574), and A Short Note on the Occurrence of Cytodites nudus in the Domestic Fowl in South Africa (pp. 577-581) both by J. Walker; Investigations into Jagziekte or Chronic Catarrhal Pneumonia of Sheep, by D. T. Mitchell (pp. 585-614); Report on Acokanthera venenata, G. Don, from the Transvaal (pp. 617-623); and On the Transmission of Hamoproteus columba, by R. Gonder (pp. 627-632).

Veterinary work in Argentina, Wehrle (Arb. K. Gsndhtsamt., 50 (1915), No. 2, pp. 164-302).—This paper presents details of veterinary work, statistics relating to domestic animals, etc., for Argentina, continuing the series previously noted (E. S. R., 34, p. 576).

Text-book of meat hygiene, R. Edelmann, trans. by J. R. Mohler and A. Eichhorn (*Philadelphia: Lea & Febiger, 1916, 3. rev. ed., pp. VI+17-452, pls. 5, figs. 161*).—This is the third revised English edition and authorized translation revised for America (E. S. R., 21, p. 163).

Fumigation of cotton seed by gaseous hydrocyanic acid, F. Hughes (Agr. Jour. Egypt, 5 (1915), No. 1-2, pp. 84-90).—The experiments reported led to the conclusion that "although minute quantities of hydrocyanic acid have been found in all samples of treated seed examined, the amount is so small that no fear need be entertained as to its proving in any way toxic. The acid appears

to be for the most part expelled or destroyed in the process of 'cooking' preparatory to the extraction of the oil.

"The quantity of hydrocyanic acid found in the cake prepared from treated seed is so small that it would in no way interfere with its use as cattle feed. No hydrocyanic acid could be detected in the partly refined oil. No alteration in its character or properties could be detected. The considerable absorption of hydrocyanic acid gas by cotton seed appears to be very largely due to the solubility of the gas in the oil contained in the seed."

The biologic reactions of the vegetable proteins.—VII, Anaphylaxis reactions between proteins from seeds of different genera of plants, H. G. Wells and T. B. Osborne (Jour. Infect. Diseases, 19 (1916), No. 2, pp. 183–193).—Continuing work previously noted (E. S. R., 34, p. 577) it is concluded that since chemically similar proteins from seeds of different genera react anaphylactically with one another, while chemically dissimilar proteins from the same seed fail to do so in many cases, the specificity of the anaphylactic reaction depends on the chemical structure of the protein molecule.

Certain nonspecific reactions obtained with antigens made from bacteria grown on serum media, J. K. OLITSKY and E. BERNSTEIN (Jour. Infect. Discases, 19 (1916). No. 2, pp. 253-259).—"The injection of serum-grown bacteria into animals for the purpose of producing immune serum for comparative serologic studies is to be avoided. Such a method results in the production of a precipitating serum v. the serum present in the media. The antiserum thus formed reacts in a nonspecific manner to various bacteria grown on serum media in regard to precipitation, agglutination, complement-fixation, and formation of cellular antibody."

A comparison of the natural hemolytic activity of fresh human sera against guinea-pig and sheep erythrocytes, H. W. Wade (Jour. Med. Research, 34 (1916), No. 1, pp. 113-119).—From the study it is concluded that natural antiguinea-pig hemolytic activity occurs in human sera with considerable regularity and uniformity of concentration. This hemolytic combination is deemed superior to the natural antisheep cell hemolysins as a serological reagent, since the latter appears less constantly and with greater variability of concentration.

The influence of exposure to X-rays upon the formation of antibodies, J. P. Simonds and H. M. Jones (Jour. Med. Research, 33 (1915), No. 2, pp. 183-196, fig. 1).—In the experiments reported rabbits were exposed daily to X-rays for from 10 to 15 minutes for a period of three weeks. Immediately following the exposure a single large dose of killed typhoid bacilli was given intraperitoneally to each animal.

The exposure to the X-rays was found to lower appreciably the formation of agglutinins. No marked difference was observed in the opsonic content and complement-fixing power of the serum of X-rayed animals compared with controls. It is deemed that the results obtained in a study of the bacteriolysins for typhoid bacilli do not warrant a positive statement. The indications are, however, that the production of bacteriolysins was not greatly interfered with by exposure to X-rays.

The effect of injections of benzol upon the production of antibodies, J. P. Simonds and H. M. Jones (Jour. Med. Research, 33 (1915), No. 2, pp. 197-211, figs. 2).—In these experiments rabbits were injected subcutaneously with a mixture of 1 part benzol and 2 parts olive oil in such doses that the animals received approximately 1 cc. of benzol per kilogram of body weight.

Sharp individual differences were noted in the effect of the injections upon the leucocytes and erythrocytes of the different animals. A depression in the production of hemolysins, agglutinins, and opsonins was observed in the injected animals, as compared with normal controls injected with the same antigen. The depression was most marked in the case of hemolysins and least so in the case of opsonins.

On the concentration of antitoxic sera, Annie Homer (Biochem. Jour., 10 (1916), No. 2, pp. 280-307, figs. 3).—The work reported shows that the advantages claimed by Banzhaf a for the one-fraction process in the concentration of sera are often vitiated by the fact that a final product is obtained which on account of the presence of an opalescent suspension, presumably euglobulin, can not be filtered except after long standing. The successful preparation of an easily filterable end product has been found to depend on the initial heating of the serum mixtures. The heating process does not cause a conversion of pseudoglobulin into euglobulin, but merely serves to complete the aggregation of the euglobulin into particles sufficiently large to admit of separation by filtration.

The uncertainty with regard to the successful heating of the serum mixtures is obviated by the addition of 1.5 per cent sodium chlorid. It is deemed possible that the addition of sodium chlorid exerts a favorable influence on the filtration process by an adjustment of the hydrogen-ion concentration of the serum mixtures.

Observations with regard to the effect of the addition of sodium chlorid to the serum mixtures have also been made and are reported in detail.

A multiple pipette for the complement-fixation test, J. M. Buck (Jour. Infect. Diseases, 19 (1916), No. 2, pp. 267-271, figs. 3).—A pipette by means of which twelve portions of either normal salt solution, complement, sensitized serum, or any of the other elements used in serological diagnosis can be distributed at one time is described, as well as a special container for the substance to be distributed and a modified test-tube rack. The multiple pipette not only permits of indefinitely greater progress with greater accuracy but also eliminates the severe eye strain resulting from the constant reading of the type of pipette generally used.

Hemolytic streptococci found in milk: Their significance and their relation to virulent streptococci of human origin, D. J. DAVIS (Jour. Infect. Diseases, 19 (1916), No. 2, pp. 236-252, figs. 2).—The results of the study reported are summarized as follows:

"Hemolytic streptococci, having a wide clear zone, occur commonly in both pasteurized and unpasteurized (certified) milk. These strains vary among themselves. They are more resistant to heat than human strains of hemolytic streptococci, and possess little or no virulence for rabbits, therefore in all probability none for man. They rapidly acidify and coagulate milk, and grow well at 20° C. They form short or long chains, but as seen in milk often appear in pairs or a chain of few elements. While they are definitely hemolytic . . ., the characteristics of the hemolytic zone on plates may vary in certain respects.

"The milk strains are different from certain strains of hemolytic streptococci found at times in diseased udders in cows. These latter resemble the strains of hemolytic streptococci from human sources, and are virulent for rabbits.

"There is no reason to consider that these organisms have any sanitary significance. The importance, however, of certain types of hemolytic streptococci in relation to epidemics of sore throat makes it necessary to study carefully all such organisms in milk. By itself the hemolytic property has no more value for identification purposes than many other characteristics, but is greatly important on account of the practical value of the blood-agar-plate method as a

Collected Studies Bur. Lab. Dept. Health N. Y. City, 7 (1912-13), pp. 114-116.

means of initial separation of human type strains from the many strains of nonhemolytic and feebly hemolytic streptococci found in milk."

A comparative study of colon bacilli isolated from horse, cow, and man, T. J. Murray (Jour. Infect. Diseases, 19 (1916), No. 2, pp. 161-174, figs. 2).— From the work reported it is concluded that the different types of strains, human, bovine, and equine, exhibit a remarkable similarity in the reactions tested, chiefly in acid production. In general the average amount of acid produced by each type tended to decrease as the complexity of the tested substance increased.

"With mannite, dextrose, and lactose, the organisms have a high point of acid production at which the larger percentage of the strains belong. The other strains for the greater part lie immediately on either side of this high point. The acid production for the larger number is confined to narrow limits. The high points of acid production do not lie far apart with dextrose, lactose, and mannite. They coincide in the case of mannite. In general with saccharose, raffinose, and salicin this high point is neither clearly shown nor definitely marked. The acid production varies greatly and is spread over a large area."

The mode of infection in pulmonary distomiasis.—Certain fresh water crabs as intermediate hosts of Paragonimus westermanii, K. NAKAGAWA (Jour. Infect. Diseases, 18 (1916), No. 2, pp. 131-142, pls. 4, figs. 2).—This is the article referred to in the paper previously noted (E. S. R., 35, p. 384).

Investigations of foot-and-mouth disease, IV, E. KALLERT (Arb. K. Gsndhtsamt., 50 (1915), No. 2, pp. 159-163, pls. 2).—This fourth contribution (E. S. R., 34, p. 879) deals with the changes which take place in the rumen of cattle affected with foot-and-mouth disease.

Mortality among grazing animals in Germany due to Simulium reptans, MATTHIESEN, PEETS, and DAHLGEÜN (Berlin, Tierärztl. Wehnschr., 31 (1915), No. 36, pp. 421-425, fig. 1; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 11, pp. 1499, 1500).—For ten years a disease has been recorded among grazing animals in the districts of Neustadtam-Rübenberge and Fallingbostel, located on the low ground near the rivers Aller and Leine, Prussia, which regularly causes the death of a large number of cattle, usually a short time after they are turned out to pasture. Horses are only rarely attacked. Investigations made regarding the disease show that the death of the animals is due to the bite of S. reptans.

Some observations on the methods of using the agglutination test in the diagnosis of disease in bovines caused by the bacillus of contagious abortion, H. R. Seddon (*Proc. Roy. Soc. Victoria*, n. ser., 27 (1915), No. 2, pp. 370-390).—The author discusses the study reported under the topics of materials required on which to found a diagnosis of contagious abortion, technique employed, and quantitative factors in the agglutination reaction.

In determining whether the relation of the quantity of pure serum to the degree of dilution or the amount of pure serum in the tube is the determining factor in agglutination of a particular serum, it is concluded that "tubes possessing the same dilution (but different quantities) of serum do not furnish parallel results. . . . Tubes containing the same quantity of serum do furnish parallel results. The agglutination titer varies with the quantity of emulsion used." The dominating factor on an agglutination system is, therefore, the quantity of serum in each tube, and not the degree of dilution.

Studies on the optimum amount of emulsion for use in the test are also reported.

Different types of streptococci and their relation to bovine mastitis, G. MATHERS (Jour. Infect. Diseases, 19 (1916), No. 2, pp. 222-235).—The author has corroborated the findings of Davis and Capps (E. S. R., 31, p. 482) that

hemolytic streptococci of human origin produce mastitis in cows when injected directly into the milk ducts.

"This mastitis may be severe, leading to a caked bag and later to a chronic inflammatory condition which results in an atrophy of the mammary gland. On the other hand, virulent hemolytic streptococci may grow and multiply in the milk ducts of a cow without causing any visible changes in the udder. The milk, however, . . . contains hemolytic streptococci and an increased number of leucocytes. These infections may persist over long periods of time in the form of a chronic mastitis.

"Streptococcus lacticus of the type used in these experiments produces a very acute inflammation of the udder when cultures are injected directly into the milk ducts. This infection... was of short duration and left the gland functionally unchanged. A nonpathogenic hemolytic streptococcus of the type commonly found in normal milk may give rise to a transitory inflammation of the udder when injected directly into the milk ducts, producing a mastitis similar in every detail to that produced by nonhemolytic S. lacticus. The presence of pathogenic streptococci and an increased number of leucocytes in milk is indicative of a mastitis, and may be the sole indication of mastitis.

"The quarters of a cow's udder under experimental conditions are apparently separate as regards infection. One quarter may be infected, while the others remain normal. Examination of the milk from each quarter of the udder is necessary before mastitis can be excluded in a suspected cow.

"In three instances of bovine mastitis, all of which were due to hemolytic streptococci with all the characteristics of the human types, no noteworthy changes in the morphology or cultural characteristics of the invading organisms were observed in frequent examinations of the milk throughout the course of the infections. The distinguishing characteristics primarily noted for each organism were still present at the last observation, and there were no modifications which might be considered as indicating a change from one type to the other. The cultural and morphological characters of *S. lacticus* and of the hemolytic streptococcus derived from normal milk did not change during the course of the udder infections which they induced."

Control and eradication of infectious mastitis in dairy herds, H. Moak (Cornell Vet., 6 (1916), No. 1, pp. 36-40).—Considerable success has been met with in the control of this disease by dipping the teats after milking in a weak solution of one of the newer high-powered antiseptics, pyxol, wescol, or hycol (one teaspoonful to 3 pints or 2 qt. of water), for six or seven seconds. Reports from several herds affected with mastitis state that from the time this treatment was started to new cases developed. The practice is now made obligatory on 12 farms furnishing certified milk for Brooklyn, N. Y.

Effects of feeding cotton seed and its products to swine, G. A. ROBERTS (Jour. Amer. Vet. Med. Assoc., 49 (1916), No. 1, pp. 12-17).—A digest of investigational work of the several divisions of the North Carolina Experiment Station during the past six years.

"While several agents [sulphate of iron, ashes, etc.] have proved efficient in prolonging the period of safe feeding of cotton-seed meal no practical means for eliminating the toxic element, or elements, has as yet been developed. The writer believes that the effect of the above agents is purely chemical in rendering the gossypol, and possibly other toxic substances, nontoxic. He has noted with others that hogs having range and rooting a great deal apparently gain minerals from the soil and forage which enable them to withstand the cotton-seed meal longer than when confined, especially when on a board floor. Since iron salts did not prevent all deaths, and that a number of iron-fed swine developed conspicuous rheumatic symptoms, the writer does not believe iron to be

the logical antidote, but has hopes that a safe method of feeding the meal to swine will be discovered." See also a previous note (E. S. R., 34, p. 79).

Feeding experiments with Bacterium pullorum.—The toxicity of infected eggs, L. F. Retter, T. G. Hull, and W. S. Sturges (Jour. Expt. Med., 23 (1916), No. 4, pp. 475–489).—"The problem of eradicating ovarian infection in the domestic fowl assumes still greater importance than heretofore in the light of data recently acquired. Not only is it of great significance to eliminate the permanent carriers of B. pullorum from all flocks of fowls from the standpoint of successful poultry breeding, but also because they constitute a possible source of danger to man.

"Eggs which harbor *B. pullorum* in the yolk in large numbers may produce abnormal conditions, when fed, not only in young chicks but in adult fowls, young rabbits, guinea pigs, and kittens. The toxicity for young rabbits is most pronounced, the infection usually resulting in the death of the animals. In kittens the most prominent symptoms are those of severe food poisoning with members of the paratyphoid group of bacteria. The possibility of infected eggs causing serious disturbances in young children and in the sick and convalescent of all ages must therefore receive serious consideration.

"Ovarian infection of fowls is very common throughout this country. Hence, a large proportion of the marketed eggs are infected with *B. pullorum*. When such eggs are allowed to remain in nests under broody hens, or in warm storage places, for comparatively few hours, they contain large numbers of the organism.

"Soft boiling, coddling, and frying on one side only do not necessarily render the yolks free from viable bacteria; therefore, eggs which have gone through these processes may, like raw eggs, be the cause of serious disturbances in persons who are particularly susceptible to such influence, and especially to infants."

Morphology of adult and larval cestodes from poultry, J. E. Gutberlet (Trans. Amer. Micros. Soc., 35 (1916), No. 1, pp. 23-44, pls. 4).—"By morphological comparison of the cysticercoids produced experimentally in flies and adult of Choanatania infundibuliformis they are shown to be identical. Morphological points noted are the presence of minute hooklets on the suckers and entire surface of scolex in C. infundibuliformis. The manner of development of uterus in the same species is by means of a blind tube which grows in size, forming pockets, and later breaks up into small compartments. In Davainea tetragona the genital pores were found to occur irregularly alternate in the proglottids. The hooks on the rostellum of D. cesticillus were found to vary in length from 8 to 12  $\mu$ . The uterus in development first appears as a solid cord of cells which becomes hollow and in growing forms pockets, filling the entire proglottid."

The studies here presented relate to those previously noted (E. S. R., 35, p. 577.) A bibliography of 26 titles is appended.

Further investigations into the etiology of the protozoan disease of turkeys known as blackhead, entero-hepatitis, typhlitis. etc., T. Smith (Jour. Med. Research, 33 (1915), No. 2, pp. 243-270, pls. 5).—"Putting together the data at hand, certain facts seem to stand out quite clearly. The parasite, from the fact of its destructive effect on the young bird's life, is poorly adapted to its young host. The process of invasion into the walls of ceca and liver is not adjusted to the discharge of parasites for passage to another host. The parasites are buried within the host lesions. Again, the cycle as observed is obviously incomplete. There is all told a remarkable want of adaptation of means to ends such as we find so fully developed in the coccidia and protozoan blood parasites, for instance.

"The evidence points to several possible theories rather widely divergent. The disease may represent a kind of aberrant parasitism, the true host being some other species. Or the parasite may undergo its normal development in the contents of the ceca, and the invasion of the tissues may be abnormal. Or there may be still other stages and an intermediate host. These views can only be definitely proved or disproved with the aid of the experimental method. The writer does not feel committed to any one of these hypotheses. The results obtained on feeding in 1913 and on exposing young artificially reared turkeys to young diseased turkeys in 1914 were not definite enough to prove that infection is direct from diseased bird to healthy, and they will require repetition and amplification.

"In casting about for a satisfactory method for raising trustworthy birds for experimental work the writer found that healthy turkeys could be reared from infected flocks by using the incubator and brooder. This procedure has made it fairly evident that blackhead is not transmitted in the egg, although more trials are needed before we can be certain of this."

Aberrant intestinal protozoan parasites in the turkey, T. Smith (Jour. Expt. Med., 23 (1916), No. 3, pp. 293-300, pl. 1).—"There are so many points of difference between the blackhead parasite and the unknown parasite of the mucous membrane as encountered in this single case, that any attempt to present them would require an elaborate restatement of what is now published. Assuming that they are different, we are confronted with the fact that, even after the blackhead parasite shall have been eliminated, the outlook for raising turkeys without some losses due to avian coccidia and perhaps other still unknown protozoan parasites is not very encouraging. Fortunately the mortality due to these aberrant parasites was low. In any case the specific sources of coccidia and other parasites must be found and dealt with."

Hasstilesia tricolor, a common parasite of rabbits in the United States, M. C. Hall (Jour. Amer. Vet. Med. Assoc., 48 (1916), No. 4, pp. 453-456).—The author erects the genus Hasstilesia for Distoma tricolor described from Sylvilagus mallurus (Leptus sylvaticus) and L. americanus by Stiles and Hassall in 1894. This is a very common intestinal parasite of rabbits in Maryland, Virginia, and the District of Columbia and is also recorded from New York and Texas.

## RURAL ENGINEERING.

Reports on irrigation for the year 1915, E. F. DRAKE and F. H. PETERS (Dept. Int. Canada Ann. Rpt. 1915, pt. 7, pp. 23).—This includes the reports of the superintendent and the commissioner of irrigation of Canada.

Venturi meter succeeds in irrigation (Engin. News, 75 (1916), No. 24, pp. 1122, 1123, figs. 3).—A description of the adaptation of this well-known device to the measurement of irrigation water is given.

Determination of the maximum storm-water flow, C. E. Grunsky (West. Engin., 5 (1914), No. 6, pp. 254-256, flg. 1).—This is a description of a new method of solving the problem of rate of maximum run-off, involving a discussion of the elements affecting its determination, the derivation of the Grunsky formula for maximum rain intensity, and tabulated data showing its application.

The formula is  $I = \frac{C}{\sqrt{t}}$ , in which I = intensity in inches per hour, t = time in

minutes, and C=a coefficient to be determined from rain records.

Determination of maximum stream flow, C. E. Grunsky (West. Engin., 7 (1916), pp. 217-219).—From the formula for storm-water flow applicable to small areas, noted above, an expression for maximum stream flow is developed,

which it is stated may be applied to even the largest streams. Examples are given based on the actual discharge of several rivers.

Control of the Colorado River as related to the protection of Imperial Valley, J. C. Allison (*Proc. Amer. Soc. Civ. Engin.*, 42 (1916), No. 5, pp. 681-709, figs. 10).—The more important details of this work are described.

The drainage of the humid and saline soils of the Egyptian Delta, É. CATZEFLIS (Egypte Contemporaine, No. 27 (1916), pp. 324-354, pl. 1).—This article deals with the technique and economics of the drainage of the humid and saline soils of Egypt.

The results of physical tests of road-building rock, P. Hubbard and F. H. Jackson, Jr. (U. S. Dept. Agr. Bul. 370 (1916), pp. 100, . 1).—This bulletin and Bulletin 347 (E. S. R., 34, p. 890) together constitute a complete revision of Office of Public Roads Bulletin 44 (E. S. R., 27, p. 587), and furnish the results of physical tests of road-building rock made in the laboratories of the United States Office of Public Roads and Rural Engineering to January 1, 1916. It has been assumed that traffic of less than 100 vehicles per day is light, between 100 and 250 moderate, and over 250 heavy.

"The ideal rock for the construction of a water-bound macadam road resists the wear of traffic . . . to that extent which will supply a sufficient amount of cementitious rock dust to bind the larger fragments in place. . . . As determined by test, cementing values [for rocks] below 25 are called low; from 26 to 75, average; and above 75, high. In general, the cementing value should run above 25. For rocks which show a low French coefficient of wear, a relatively high cementing value is more necessary than for those which have a high French coefficient. . . .

"Experience has shown that in general the following table of limiting values for the French coefficient of wear, toughness, and hardness may be used in determining the suitability of a rock for the construction of the wearing course of a macadam road:

Limiting values of physical tests of rock for water-bound macadam road construction.

	Limits of tests.							
	Character of traffic.	French coefficient of wear.	Tough- ness.	Hard- ness.				
Moderat	0	5-8=(5-8 per cent wear)	5–9 10–18 Over 18	10-17. Over 14. Over 17.				

"As a result of comparing hardness and toughness tests of some 3,000 samples, ... when any given value for toughness falls within certain limits which define the suitability of the material for macadam road construction under given traffic conditions, the corresponding value for hardness will fall within similar limits for hardness. . . . The great majority of samples having a French coefficient of wear of from 5 to 8 and a hardness of over 17 are granites, quartzites, and hard sandstones, which are unsuited for use in the wearing course of water-bound macadam roads due to their lack of binding power.

"For broken-stone roads which are maintained with dust palliatives, the same limits for French coefficient of wear and toughness should hold as for ordinary macadam roads. In bituminous work in some cases it is advantageous to use a rock of relatively high absorption rather than one with low absorptive quali-

ties, owing to a better adhesion of the bituminous material by a partial surface impregnation of the rock."

The following table "may be used as a general guide for minimum limits of French coefficient of wear and toughness in connection with bituminous brokenstone roads."

Minimum limits of physical tests of rock for bituminous-road construction.

	Light to moderate t	raffic.	Moderate to heavy traffic.				
Type of road.	French coefficient of wear.	Tough- ness.	French coefficient of wear.	Tough- ness.			
Broken stone with bituminous carpet. Bituminous broken stone with seal coat. Bituminous concrete with or without seal coat.	5=(not over 8 per cent wear). 7=(not over 5.7 per cent wear).	} 5 7	{7=(not over 5.7 per cent wear).  10=(not over 4 per cent wear).	} 10			

Construction and maintenance of earth roads, L. V. Edwards (State Col. Wash., Dept. Ext. Bul. 20 (1916), pp. 35, figs. 29).—This bulletin is intended to give some suggestions to road supervisors and others interested in improved roads as to how to construct and maintain earth roads. The subjects dealt with are grading, grades, widths, drainage, and maintenance.

Brick roads, V. M. Peirce and C. H. Moorefield (U. S. Dept. Agr. Bul. 373 (1916), pp. 40, pls. 12, figs. 4).—A revision of Bulletin 246 (E. S. R., 33, p. 686).

Rules and regulations of the Secretary of Agriculture for carrying out the Federal Aid Road Act. D. F. HOUSTON (U. S. Dept. Agr., Office Sec. Circ. 65 (1916), pp. 24).—The text of the act (E. S. R., 35, p. 200), and of the rules and regulations, is given.

Factors of apportionment to States under Federal Aid Road Act appropriation for the fiscal year 1917 (U. S. Dept. Agr., Office Sec. Circ. 62 (1916), pp. 2).—This circular presents the factors of apportionment and the amounts apportioned to each State for the fiscal year 1917 under the Federal Aid Road Act.

Fifth, sixth, seventh, and eighth annual reports of the state roads commission [of Maryland] for the years 1912-1915 (Ann. Rpts. State Roads Com. Md. 5-8 (1912-1915), pp. 175, pls. 22).—This reports the activities and expenditures of the commission for the years 1912-1915.

Report of the State Highway Department of Washington for the period October 1, 1912, to October 1, 1914, W. R. Roy (Rpt. State Highway Dept. Wash., 1912–1914, pp. 192, figs. 42).—This is an outline of the various phases of work undertaken by the Washington Highway Department, together with a survey of highway conditions in the State and practical suggestions and information.

Bridge foundations, W. Burnside (New York: D. Van Nostrand Co., 1916, pp. VIII+139, figs. 32).—This book deals with foundations for abutments and piers of bridges crossing rivers or other waters.

"The different kinds of foundations in common use and the methods by which they are placed in position are described. The conditions suited to each kind are noted and where necessary and possible the principles of design are indicated. Next to nothing, however, is said with regard to cost and in reference to plant."

The subject matter includes chapters on the foundation bed, abutment foundations, pier foundations, piled foundations, dams, screw piles and screw

cylinders, well foundations, standard caissons, open caissons, pneumatic caissons, and the effects of compressed air,

Tables giving data on loads on foundations, skin friction, properties of materials, pile-bearing formula, steel sheet piling, quantities and cost for the pier of the American River bridge, decompression periods, and stage decompression are appended.

Economy in bridge design and construction, H. W. JOYCE (Calcutta: Bengal Secretariat Book Depot, 1915, pp. [IV]+98, pl. 1, figs. 55).—This is a series of six lectures on the subject delivered to the students of the Sibpur Engineering College.

Value of the high-pressure steam test of Portland cements, R. J. Wig and H. A. Davis (U. S. Dept. Com., Bur. Standards Technol. Paper 47 (1915). pp. 34, pls. 2, figs. 4; abs. in Sci. Abs., Sect. B—Elect. Engin., 19 (1916), No. 220, p. 127).—Investigations made to establish "if possible, a relationship between the behavior of Portland cements in high-pressure steam and their physical properties under normal conditions of use and exposure and to determine what value, if any, the high-pressure steam test has as a means of detecting unsoundness which might cause a weakening or disintegration of the cement or concrete" are reported.

"The qualitative high-pressure steam test used consists of subjecting an ordinary soundness pat, which has been stored for 24 hours in a damp closet, to a steam pressure of 300 lbs. per square inch for at least one hour, the total time in the high-pressure boiler being three hours. A cement was said to pass this test when it exhibited no cracking, warping, or disintegration on examination after the treatment.

"The quantitative high-pressure steam test consists of molding six briquettes of neat cement at normal consistency, storing these test pieces 24 hours in a damp closet, then subjecting three of them to an atmosphere of steam at 300 lbs. pressure for at least one hour; the total time in the high-pressure boiler being three hours. The briquettes (both treated and untreated) are then broken in a shot-testing machine. A cement was said to pass this test when the treated briquettes exhibited greater strength than the untreated ones."

The following conclusions are drawn from the results obtained:

"The high-pressure steam test should be made on all cements that are incorporated in cement, mortar, or concrete products that are to be cured in steam at pressures above atmospheric. The high-pressure steam test may be of value as forecasting the behavior of neat cement or a very rich mortar when exposed under normal conditions in dry air, but it will not forecast the behavior of cements in concretes as normally exposed. The cement passing the high-pressure steam test is not superior in cementing quality, as determined from the compressive strength of concretes, to cement that fails to pass this test. The cement passing the high-pressure steam test does not make more permanent or durable concrete than cement which meets the requirements of the standard specification, but fails to pass this test. Cement failing to pass the standard specification atmospheric steam test, but meeting the other requirements of the standard specification shows in some instances a normal strength in concrete. For practical work under normal conditions of construction the results of this investigation fail to show that the high-pressure steam test is of value as a means of determining the ultimate soundness of concrete."

Testing the belt power of a tractor, E. C. GEE (Power Farming, 25 (1916), No. 6, p. 9, figs. 2).—This is a brief illustrated description of the prony brake test as applied to a tractor.

Mechanical tillage experiments at Grignon, France, in 1914 and 1915, Brétignière and Ringelmann (Prog. Agr. et Vit. (Ed. l'Est-Centre), 36 (1915), No. 23, pp. 532-536; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 8, pp. 1093-1095).—Experiments begun in 1913 with a Flemish plow drawn by oxen, a tractor and plow outfit, a motor plow, two rotary cultivators, and two tractor and cable outfits are reported. The soil was a shallow calcareous clay in the first set of experiments. After wheat, a catch crop of white mustard was sown and plowed in by the various machines, one on each plat, while one plat was plowed by a Flemish double "turnwrist" plow drawn by oxen, after which Grey Houdan oats were sown on all of them. In the second series the soil was fairly deep loam, with oats following lucern. The yields are shown in the following table:

Crop results after mechanical tillage.

		First series.				Second series.				
Kind of implement.	Straw.	Grain.	Chaff, etc.	Total.	Ratio of straw to grain.	Straw.	Grain.	Chaff, etc.	Total.	Ratio of straw to grain.
Flemish plow drawn by oxen. Tractor and plow. Motor plow Windlass tractor Tractor hauling on cable. Rotary cultivator (1). Rotary cultivator (2).	Lbs. per acre. 2,750 3,360 3,360 2,469 2,542	1,948	803 661	Lbs. per acre. 5, 411 6, 111 6, 430 4, 548 4, 758	141:100	3, 379 2, 989 3, 569 3, 212	3, 155 2, 632 3, 279 2, 766	625	7, 159 6, 256 7, 426 6, 625	111:100 107:100 115:100 109:100 116:100 120:100

In all the machine-tilled plats in the first series the ratio of straw to grain was greater than in the one plowed by oxen. In the second series the plat plowed by the windlass tractor yielded a crop similar in quantity and ratio of straw to grain to that obtained by the Flemish plow.

In both fields the rotary digger gave lower yields than the Flemish plow, while the results of the tractor and plow and motor plow differed in the two fields. In the first field the crops were heavier than those obtained on the work of the Flemish plow, while in the other field they were inferior. It was also found that in the first field the ground was not too moist and it has been plowed as well by the tractor as by the Flemish plow and decidedly better than by the motor plow. In the tractor-plowed plat the white mustard had been turned in better than by the Flemish plow. On the whole the plats plowed by the tractor and the motor plow were better prepared than the plat worked by oxen. "In the second field, on the other hand, the ground was wet; the work of the tractor left room for criticism while that of the motor plow was quite unsatisfactory."

Dust explosions and fires in grain separators in the Pacific Northwest, D. J. PRICE and E. B. McCormick (U. S. Dept. Agr. Bul. 379 (1916), pp. 22, pls. 11).—Field and laboratory experiments on the causes of dust explosions in grain separators conducted in cooperation with the University of Idaho and in consultation with the Washington Experiment Station (E. S. R., 32, p. 386) are reported, together with descriptions of preventive devices developed as a result of the investigation.

It was found that explosions were generally distributed among all types of separators, both steel and wood, and that fires occurred also in the combination

type. Of 117 fires 95 were dust explosions, and of 108 fires 82 originated back of the cylinder or very near that point. "About 75 per cent of the occurrences were assigned to the presence of static electricity and to smut explosions. . . . The investigations show conclusively that the presence of a hot box is not essential in order that an explosion may take place. . . .

"As a result of the investigations . . . it is believed that a complete system of electrical connection from all of the moving parts to a common wire, and a thorough grounding of this common wire, will prevent a large percentage of the fires that are due to the presence of static electricity and an explosive mixture of smut dust and air." The use of a suction fan attached to the top of the separator and near the cylinder which exhausts from above the cylinder and from below the fan is also advocated.

An automatic fire extinguisher which was tested and found to be satisfactory is also described. This consists essentially of a tank mounted on top of the separator and containing a bottle of sulphuric acid and water containing soda. Other accessories are a discharge pipe extending throughout the separator and fitted with spray nozzles, a tripping mechanism, and a set of fuses mounted in a wire line.

"The presence of sufficient heat within the separator will melt one of the fuses. This breaks the wire line, releasing the trigger, which frees the tripping mechanism, causing a hammer within the tank to strike a blow sufficient to break the bottle. The discharge of the sulphuric acid into the water containing soda causes the formation of carbon dioxid, which generates sufficient pressure to force the water through the discharge pipe and the nozzles to all the crevices of the separator. . . .

"The locations [of fuses] will vary with each machine, and must be selected so that the fuses are sure to be reached by the flame or the heat, but not so placed that the wire connecting them is likely to be broken by the straw or by the moving parts of the separator.

"The location of the nozzles depends upon the construction of the machine, but the following points should be observed:

"Locate one nozzle directly above the cylinder, if possible; if not, place it so that the beater will help diffuse the spray from that nozzle. Run the pipe line along underneath the roof of the separator, with the nozzles pointing downward. Install a sufficient number of nozzles along this line, and so locate them that every chamber in the separator is thoroughly served by a nozzle. Particular pains should be taken to serve dead air spaces, as it is in these that dust is likely to accumulate. As the stacker end of the machine is less likely to contain any closed chambers, it is probable that, in most types of machines, the nozzles at this end may be 30 in. or more apart. The last nozzle along the pipe line and within the separator should be just above the end of the shakers."

Combination barns for prairie farms, A. R. Greig and A. M. Shaw (Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 1 (1915), pp. 54, figs. 21).—This bulletin describes and illustrates the structural details of four combination barns and gives bills of materials.

Dairy barns, ice and milk houses for prairie farms, A. R. Greig and A. M. Shaw (Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 2 (1915), pp. 66, figs. 20).—This bulletin describes and illustrates the structural details of four dairy barns and two ice and milk houses.

Beef cattle barns for prairie farms, A. R. Greig and A. M. Shaw (Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 3 (1915), pp. 53, figs. 18).—This bulletin describes and diagrammatically illustrates a beef cattle breeding barn, feeding shed, and feeding barn and discusses details of roof framing, mangers, stalls, a portable grain table, and a portable feeder.

Horse barns for prairie farms, A. R. Greig and A. M. Shaw (Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 4 (1915), pp. 50, figs. 16).—This bulletin describes and illustrates the structural details of four horse barns and discusses the details of roof framing, stalls, and ventilation.

Sheep barns for prairie farms, A. R. Greig and A. M. Shaw (Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 5 (1915), pp. 34, figs. 13).—This bulletin describes and illustrates the structural details of four sheep barns and of feeding devices and gives bills of materials.

Piggeries and smokehouse for prairie farms, A. R. Greig and A. M. Shaw (Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 6 (1915), pp. 38, figs. 13).—This bulletin describes and illustrates the structural details of two permanent piggeries, a portable piggery, and a smokehouse, and gives bills of materials.

Poultry houses for prairie farms, A. R. Greig and R. K. Baker (Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 7 (1915), pp. 35, figs. 12).—This bulletin describes and illustrates the structural details of one permanent and two portable poultry houses, trap nests, feed hoppers, and a coop for a setting hen, and gives bills of materials.

The pullet laying house, G. R. Shoup (Washington Sta., West. Wash. Sta. Mo. Bul. 4 (1916), No. 4, pp. 12-20, figs. 2).—This describes the construction of a pullet laying house adapted to Washington conditions.

Commercial poultry house equipment, Mr. and Mrs. G. R. Shoup (Washington Sta., West. Wash. Sta. Mo. Bul., 4 (1916), No. 5, pp. 3-11, figs. 4).—This article describes the necessary furnishings and equipment for the efficient handling of laying pullets.

Implement sheds and granaries for prairie farms, A. R. Greig and A. M. Shaw (Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 8 (1915), pp. 38, figs. 10).—This bulletin describes and illustrates the structural details of a portable granary, two permanent granaries, and two implement sheds, and gives bills of materials.

Silos and root cellars for prairie farms, A. R. Greig and A. M. Shaw (*Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 9* (1915), pp. 38, figs. 17).—This bulletin describes and illustrates the structural details of two stave silos and a root cellar and gives bills of materials.

Silos and silage, H. L. BLANCHARD (Washington Sta., West. Wash. Sta. Mo. Bul. 4 (1916), No. 4, pp. 2-10, figs. 7).—This is a brief description of the stave, wooden hoop, concrete, and pit silo, and methods of silo filling.

Houses for prairie farms, A. R. Greig and L. B. Beale (Brit. Columbia Dept. Lands, Forest Serv., Farm Build. Ser. Bul. 10 (1916), pp. 70, figs. 29).—This bulletin describes and diagrammatically illustrates six farmhouses, gives bills of materials, and discusses septic tanks and methods of laying out farms.

Modern plumbing illustrated, R. M. Starbuck (New York: The Norman W. Henley Publishing Co., 1915, 3. ed., rev. and enl., pp. 407, figs. 58; rev. in Engin. News, 75 (1916), No. 24, pp. 1134, 1135).—This book contains 58 figures illustrating the details of different types and methods of plumbing. It is designed to cover the entire field of plumbing as far as possible. "It takes up not only plumbing as practiced in towns and cities under strict plumbing regulations, but plumbing construction under conditions obtaining in country districts, where the problems which arise are often of an entirely different nature, and where there is not in existence any public regulation of sanitary work.

"The subjects considered cover a variety of lines of work, including fixture work in detail, the construction of the drainage and vent systems in detail, and complete plumbing systems of buildings of various kinds. The work is designed essentially to cover subjects pertaining to drainage alone, but it is clear that in

many instances the subject of water supply is closely associated with the drainage problem, and the author has therefore deemed it advisable in several instances to go somewhat into the general subject of water supply. This is especially true of country plumbing systems and of the systems of large city buildings."

Sewage disposal for country homes, F. M. White and E. G. Hastings (Wis. Col. Agr. Ext. Serv. Circ. 60 (1916), pp. 15, figs. 12).—This is a popular illustrated discussion of the subject. See also a previous publication from the Wisconsin Station by Ocock and Wright (E. S. R., 28, p. 86).

### RURAL ECONOMICS.

Labor requirements of crop production, T. P. COOPER, F. W. PECK, and A. Boss (Minnesota Sta. Bul. 157 (1916), pp. 55, figs. 2).—In 1902, cost-of-production studies were started in three counties in Minnesota. Cost data were gathered by personal visits to farms, and 15 farms were selected in each locality which were visited daily by an agent to obtain labor records and weight of feeds and dairy products. These data were collected yearly since that date for 10 years, although the number of farms was reduced to 8 in each locality. As a result of the studies, data were obtained as to the average annual hours of labor required per acre in producing various field crops, as follows:

Average annual hours of labor per acre required in producing field crops, 1902-1912.

Kind of crop.		Northfield, Rice County.		Marshall, Lyon County.		Halstad, Norman County.		Average, all farms.	
	Man.	Horse.	Man.	Horse.	Man.	Horse.	Man.	Horse.	
Wheat, shock-threshed. Oats, shock-threshed. Barley, shock-threshed. Fall rye, shock-threshed. Flax, stack-threshed. Corn, husked. Fodder corn, cut, shocked, and stacked. Silage. Hay, timothy and clover, first crop. Hay, timothy and clover, two cuttings. Hay, wild. Timothy, cut for seed. Clover, cut for seed. Hay, millet. Hemp. In commenting upon the amount of labor required, the authors make the following statement:

"Increased productivity per laborer may be obtained either by extending the farm operations or by increasing the yields per acre. The extensive type of agriculture is based on the distribution of a man's labor over the greatest possible crop acreage, thus obtaining large productivity per labor unit. It is typified by the use of large-capacity machinery and of mechanical power such as steam or gasoline. In this type of agriculture each man performs a maximum of service through the aid of equipment; that is, of capital invested in equipment. . . .

"The gross returns from each unit of labor used in crop-production may increase to the point of maximum yields. . . . Additional labor should be utilized

on crops only to the point where yields give increased net returns. When this point is reached, it is better management to apply this labor to additional acres, and thus obtain a maximum return for the additional units applied, than to apply additional labor to the crop on the same land and obtain merely equal returns. In other words, if the returns for each unit of additional labor on a given acreage do not show increase, the operation should become more extensive."

Data as to the hours of labor required in marketing farm crops and a comparison of shock-threshing v. stack-threshing are also given.

Waste land and wasted land on farms, J. S. Ball (U. S. Dept. Agr., Farmers' Bul. 745 (1916), pp. 18, figs. 12).—The author has classified the non-productive farm areas as follows: Land unnecessarily taken up by farm buildings and lots, unnecessary lanes and roads, fence rows, open ditches, headlands, or turning spaces bordering fields and terraces; the part of any public road included in a farm area; land rendered untillable by swamps, rocks, etc.; woodland not yielding salable products; and uneconomic pasture land.

He discusses these various types in general and with special reference to information obtained in connection with farm management surveys on 1,703 farms, in nine States. Wide variations in the percentage of the total farm acreage occupied by nonproductive areas were found, both between different regions and on individual farms in the same locality.

Size of farm business, O. R. Johnson and W. E. Foard (Missouri Sta. Bul. 140 (1916), pp. 3-40, figs. 12).—This bulletin is the second based on data secured in a survey of four townships in the western part of Johnson County (E. S. R., 32, p. 791). Among the conclusions reached by the authors from this study are the following:

"There are several factors which play a part in determining the size and profitableness of the farm business. First in importance in a diversified farming region is the number of acres operated. The larger farms have a more favorable distribution of capital than the smaller farms. They have as large a percentage of tillable ground and less waste land than the small farms. More of the large farm is kept in grass. The large farm is more heavily stocked with live stock other than work stock. One animal unit is kept for each 6.6 acres of crops on the small farm while only 4.8 crop acres are grown for each animal unit on the larger farm.

"The operator of the larger farm is employing his men, horses, and equipment more efficiently than is the man on the smaller farm. . . . The horse on the large farm cares for 21.2 crop acres while on the small farm he has only 7.3 acres to care for. . . .

"The receipts and expenses per acre are practically the same on large and small farms. . . . The large farm seems to be able to get better results from the feeding of cattle and the return from feeding hogs are at least as good. . . .

"The labor income on a certain-sized farm is limited by the capital investment. Some farms are too heavily capitalized and others do not have enough capital invested. The most successful farms in each group have an investment of from \$70 to \$95 per acre. . . .

"The man with a low capital investment per acre is giving so much attention to grain farming that his system does not give him enough productive labor. Where the capital is larger, the farmer is able to keep more live stock and thus secure more regular employment. This influences his labor income to quite an extent."

The farmer's income, E. A. GOLDENWEISER (U. S. Dept. Agr., Farmers' Bul. 746 (1916), pp. 7, fig. 1).—This study is based upon the data available regarding farmers' incomes in the reports of the Census and the investigations of the Office of Farm Management and the States Relations Service.

From a study of the Census data, dealing with 6,362,000 farmers, the author concludes that the gross income of the farmer is \$1,236 per farm, out of which he pays \$512 in farm expenses, leaving a net earning of \$724 available for family expenses, payments on mortgage, and savings. After deducting interest on the investment at 5 per cent, there is left \$402 as labor income produced by the family.

The investigations of the Office of Farm Management indicate that the average earnings of 4,018 farm families were \$952, of which \$400 represented the value of the house rent, food, and fuel supplied by the farm. The data obtained through the farm management demonstrations of the States Relations Service indicated that the average labor income on 4,400 farms was approximately \$800.

The author commenting on these data states that "the average farm family makes approximately as much for its labor as the average industrial family, but owing to the lower cost of living on the farm and the interest earned by the farm investment, the average farm family occupies a much more secure economic position than does the average city family."

The farmer's income, E. A. GOLDENWEISER (Amer. Econ. Rev., 6 (1916), No. 1, pp. 42-48, fig. 1).—This article includes a large portion of the above data.

Costs and sources of farm-mortgage loans in the United States, C. W. Thompson (U. S. Dept. Agr. Bul. 384 (1916), pp. 16, pls. 5).—In this publication data are given as to the average interest rate and the average annual commission by States for farm-mortgage loans, and the proportion of the total mortgages in each State distributed according to the rate of interest paid. Data are also given showing the percentage of the total farm mortgages held by life insurance companies and by banks, factors which influence the terms on farmmortgage loans, the need for improved facilities, and the desirability of State and Federal legislation.

The author summarizes his conclusions as follows:

"Being given a properly organized credit system, it is believed that the farmer who adopts business methods in his farming and thus shows himself worthy of credit will have adequate opportunity to secure it on reasonable terms. The farmers' need in connection with mortgage credit is to obtain investment capital for relatively long periods of time, on suitable terms of repayment, and at the lowest cost consistent with business policy. A properly organized system should supply this need, and, under suitable Federal regulation and control, should protect the farmer against the unreasonable charges now prevailing in many localities."

Some observations on the bulk handling of grain for California, B. H. Crocheron and C. J. Williams (California Sta. Circ. 152 (1916), pp. 24).—The advantages and disadvantages of handling grain in bulk and in sacks are discussed, and data on the cost of handling grain by these methods are given. The cost of handling sacked grain after harvesting is estimated at \$3.915 per ton as compared with \$2.90 for bulk handling.

Rules and regulations of the Secretary of Agriculture under the United States Cotton Futures Act of August 11, 1916 (U. S. Dept. Agr., Office Sec. Circ. 64 (1916), pp. 27).—This circular contains rules and regulations promulgated by the Secretary of Agriculture relative to the United States Cotton Futures Act (E. S. R., 35, p. 307), as well as a copy of the act itself.

Agricultural associations and the war, P. Sagourin (Ann. Sci. Agron., 4 ser., 4 (1915), No. 10-12, pp. 382-397).—In this article are discussed the influence of the war upon the French agricultural associations and some of the functions performed by them under war conditions.

Rome's fall reconsidered, V. G. SIMKHOVITCH (Polit. Sci. Quart., 31 (1916), No. 2, pp. 201-243).—In this article the author points out the influence of the agricultural practice and the methods of holding land upon the decline of the Roman Empire.

Monthly crop reports, July and August, 1916, (U.~S.~Dept.~Agr.,~Mo.~Crop~Rpt.,~2~(1916), Nos.~7,~pp.~61-72; 8,~pp.~73-84, figs.~8).—These numbers contain the usual data relative to acerage and condition of the principal crops, average prices paid to producers, estimated farm value, the range of prices of agricultural products at important markets, and miscellaneous data.

No. 7.—This contains a statement relative to the amount of commercial fertilizers sold in the cotton States, a special report on honey yields and prospects, and a review of the tobacco situation and the condition of truck crops for canning. In commenting regarding the prices of wool the following statement is made:

"The average price paid to producers of the United States for unwashed wool in the past month was 28.7 cts. per pound, which compares with 23.7, 18.4, 15.6, 18.7, 15.5, and 19.5 cts., respectively, in June of the past 6 years. . . . The average weight of wool per fleece this year is abount 6.92 lbs."

No. 8.—Special articles are included on the commercial acreage and production of onions, the acreage in watermelons and cantaloups in 1915 and 1916, receipts and exports of Durum wheat, and the largest yield per acre of various crops produced on single fields or plats in different parts of the United States.

### AGRICULTURAL EDUCATION.

School credit for home practice in agriculture, F. E. Heald (U. S. Dept. Agr. Bul. 385 (1916), pp. 27).—The author discusses (1) methods for teachers' use in giving rank for home work in agriculture and applying that rank with proper weight to the general scholarship average of the pupil, and (2) the basis of such rank or credit for the benefit of school officials who desire to introduce home practice in agriculture as an educational feature into rural schools. Supplementay tables of labor requirements and selected club records of boys' and girls' work are included.

Public elementary schools and food supply in war time (Jour. Bd. Agr. [London], 23 (1916), No. 1, pp. 33-40).—This is the text of a memorandum issued by the English Board of Education, upon request of the president of the Board of Agriculture and Fisheries, to local education authorities, school managers, teachers, parents, and others interested in the work of elementary schools, calling attention to the need for maintaining and increasing the supply of home-grown food of all kinds. The memorandum, without giving detailed suggestions for carrying them on, briefly indicates some minor industries and occupations for increasing the food supply which have been or can be taken up in connection with rural and semirural schools, such as gardening, keeping live stock, poultry, rabbits, bees, pigs, and goats, making jam, evaporating and bottling fruits, and the drying of savory herbs in connection with cookery classes, collection of wild fruits, etc., and farm handicraft.

[State-aided vocational agricultural education in 1915] (Ann. Rpt. Bd. Ed. [Mass.], 79 (1916), pp. 185-193, 293-299, 320, 321; Bul. Bd. Ed. Mass. No. 54 (1916), pp. 19).—This report is devoted to the present achievements of the two county agricultural high schools in Bristol and Essex Counties, respectively, and the future prospects of this type of school, and to statistical data on the three vocational agricultural schools and 13 agricultural departments in selected high schools, with reference to receipts and expenditures, teachers, student enrollment, distribution of graduates, activities, including judging and

other contests, earnings of agricultural pupils from farm and other work for the years 1912-1915, inclusive, and project work.

Short courses (Agr. Gaz. Canada, 3 (1916), No. 4, pp. 310-324, figs. 4).—This is a review of the short courses in agriculture and home economics offered in the Provinces of Prince Edward Island, Nova Scotia, Quebec, Manitoba, and Saskatchewan.

School garden plans for 1916 (Agr. Gaz. Canada, 3 (1916), No. 4, pp. 355-361).—The plans for school garden work for 1916 in the Provinces of Prince Edward Island, Nova Scotia, Ontario, Manitoba, Saskatchewan, and British Columbia, are outlined.

A school garden organization, F. W. Bates (Agr. Gaz. Canada, 3 (1916), No. 5, pp. 459-462, figs. 4).—A sketch of the organization and development of the work of the Lost River Municipal School Garden Association in Saskatchewan as an illustration of the success of school gardening organized as a community project.

Report of the Minister of Agriculture, Industry, and Commerce for 1914, M. E. De Queiroz Vieira (Relat. Min. Agr. Indus. e Com., Brazil, No. 1 (1914), pp. XXXIV+204, pls. 41).—This report includes an account of the progress in 1914 of agricultural education and reearch institutions in Brazil, comprising the Higher School of Agriculture and Veterlary Medicine at Rio de Janeiro, a secondary or theoretical-practical school of agriculture, 8 agricultural apprentice schools, 1 permanent dairy school, 5 experiment stations, of which 2 are in process of organization; 5 demonstration fields, 2 sericultural stations, 3 zootechnical stations, 4 model stock-breeding farms, and the botanical garden, national museum, and forest nursery, and of agricultural extension work.

The Danish people's high school including a general account of the educational system of Denmark, M. Hegland (U. S. Bur. Ed. Bul. 45 (1915), pp. 182).—Part I of this bulletin gives a general account of the educational system of Denmark. Part II deals with the origin, growth, life, aims, curricula, methods, influence, and results of the people's high schools in Denmark, gives brief accounts of similar schools in Norway, Sweden, Finland, Germany, England, and the United States, and discusses the adaptation of these schools to American conditions. Tables, giving statistics of students, teachers, and number of hours of instruction devoted to each subject in a five months' course in the people's high schools and agricultural schools in Denmark, and a bibliography are appended.

Activities of the Italian Colonial Agricultural Institute, G. B. Gioli (Agr. Colon [Italy], 10 (1916), No. 1-2, pp. 94-104).—This is a report, by the director, on the regulations, staff, curriculum, experimental work, and finances for 1914–15 of the Italian Colonial Agricultural Institute at Florence.

The Bavarian forestry schools, Esslinger (Ztschr. Forst. u. Jagdw., 47 (1915), No. 9, pp. 568-572).—The author discusses the training required for admission to the forest management and forest protection service, including the new regulations requiring a four-year course in a forest school after the completion of the seven-year Bavarian public school course.

Regulations for the training of teachers of agricultural home economics (Min. Bl. K. Preuss. Verwalt. Landw., Domänen u. Forsten, 10 (1914), No. 5, pp. 80-109).—Detailed information is given concerning the training of agricultural housekeeping teachers in Prussia, including (1) the admission requirements; (2) an outline of the one-year course of instruction in cooking, baking, preserving, housekeeping, laundering, sewing, physics, chemistry, botany, the origin, nutritive and economic value, utilization, and adulteration of foodstuffs, marketing, hygiene and sanitation, psychology and pedagogy, civics and rural welfare, household accounts and bookkeeping, animal husbandry, including pig

raising, dairying, poultry raising, and fruit, flower and vegetable gardening; (3) time schedules showing the distribution of subjects and time devoted to theoretical and practical instruction in each; (4) exercises in cooking, baking, and preserving; and (5) written and theoretical-practical oral examination requirements, the former including two theses on methods of teaching and agricultural and home economics subjects, respectively. This training is given in the agricultural seminars of six of the farm and home management schools designated by the Minister of Agriculture, Domains, and Forests, viz, at Obernkirchen, Maidburg, Bad Weilbach near Flörsheim, Mallinckrodthof at Paderhorn, and Luisenhof at Bärwalde.

Scientific informations (Netherlands East Indian San Francisco Com., Dept. Agr., Indus. and Com., Essay No. 8 (1914), pp. 91, pls. 18).—Part 1 of this pamphlet gives a history of the Department of Agriculture, Industry, and Commerce of Netherlands East India, and an account of its present organization and work. Part 2 deals with the history and work of private experimental stations, the cost of which is borne privately but which nevertheless form a part of the agricultural department or are in some way connected with it.

### MISCELLANEOUS.

Annual Report of Iowa Station, 1915 (Iowa Sta. Rpt. 1915, pp. 22).—This contains the organization list and a report by the director and vice director on the work of the station, including a financial statement for the fiscal year ended June 30, 1915.

Twenty-ninth Annual Report of Nebraska Station, 1915 (Nebraska Sta. Rpt. 1915, pp. XXXVII, figs. 6).—This contains the organization list, a report as to the work and publications of the year, a report of the extension service of the college of agriculture, and a financial statement for the period ended June 30, 1915. Data as to animal husbandry and dairying are abstracted elsewhere in this issue.

Monthly bulletin of the Western Washington Substation (Washington Sta. West. Wash. Sta. Mo. Bul., 4 (1916), Nos. 4, pp. 20, figs. 10; 5, pp. 16, figs. 4).—These numbers contain brief articles on the following subjects:

No. 4.—Silos and Silage, by H. L. Blanchard (see p. 690); Summer Pruning, by J. L. Stahl; and The Pullet Laying House, by G. R. Shoup (see p. 690).

No. 5.—Market for Mole Skins, by W. A. Linklater; Commercial Poultry House Equipment, by Mr. and Mrs. G. R. Shoup (see p. 690); Rye in Western Washington, by E. B. Stookey; Black Spot Canker on the Pear, by A. Frank; Select Plants for Potato Seed, by J. L. Stahl; and Molting, by Mrs. G. R. Shoup.

Successful farming, F. D. Gardner (Philadelphia: J. C. Winston Co., 1916, pp. 1088, pls. 9, figs. 452).—This treatise is termed "a ready reference on all phases of agriculture for farmers of the United States and Canada." It is divided into ten main parts, viz, soils and soil management; farm crops; horticulture, forestry, and floriculture; live stock farming (animal husbandry); dairy farming (dairy husbandry); farm buildings and equipment; farm management; plant and animal diseases, insect enemies and their control; home economics and agricultural education; and tables of weights, measures, and agricultural statistics. Many of the chapters are contributed by members of the instruction staff of the Pennsylvania College and other institutions.

The autobiography of a farm boy, I. P. Roberts (Albany, N. Y.: J. B. Lyon Co., 1916, pp. IV+331, pls. 7).—This autobiography gives considerable space to the author's work at the Iowa College and Cornell University, including graphic accounts of some of the conditions and difficulties encountered in organizing agricultural instruction and research in the pioneer days at these institutions. The introduction is by Dr. L. H. Bailey.

### NOTES.

Connecticut College and Stations.—W. M. Esten, who has previously served on both the college and Storrs Station staffs as bacteriologist, has been transferred wholly to college work. Miss C. J. Mason, assistant bacteriologist in the station, has also been transferred to college work. Miss E. B. Whittlesey, herbarium assistant of the State Station, resigned October 1.

Georgia College and Station.—In the college, Dr. L. M. Roderick, instructor in veterinary medicine, resigned August 1, and F. H. Denniss, cooperative field agent in dairying, on October 15. I. W. Arthur has been appointed instructor in animal husbandry, effective September 1, and W. C. Burkhart, D. V. M., instructor in veterinary medicine, effective October 15.

C. A. Wells has resigned as chemist in the station, effective November 1.

Purdue University and Station.—P. R. Edgerton, W. R. Palmer, and O. H. Anderson have resigned, the first named to become a county agent in Illinois, and the remainder to take positions as farm managers. S. P. Smyth has resigned as instructor in poultry husbandry. R. S. Thomas has been appointed assistant in soils and W. R. M. Scott as assistant in farm crops. C. D. Kinsman has been transferred to extension work in rural engineering and C. C. Cunningham has been appointed in charge of drainage work. H. W. Gregory, assistant in dairying in the South Dakota College, has been appointed assistant in dairying. F. H. Beach has been transferred to extension work in horticulture and W. H. Stevenson and F. J. Sutton have been appointed instructors in that subject. H. C. Paine, D. V. M., has been appointed instructor in veterinary science and associate veterinarian in the station and will have charge of the testing of commercial serums.

Maryland Station.—Soil investigations under a special state appropriation have been begun, with A. G. McCall in charge, P. E. Richards as laboratory assistant, and S. W. Phillips as field assistant. R. L. Hill, Ph. D., has been appointed biochemist in dairy research.

Minnesota Station.—The station has recently adopted the policy of regarding all research assistants who devote at least one-half time to work on station projects as members of the staff. Under this plan the following additions to the staff were made at the opening of the present fiscal year: A. M. Gurjar, S. Sato, R. A. Thuma, and A. J. Wuertz, in agricultural biochemistry; J. C. Gillilan and Frank Robotka, in agricultural economics; M. N. Levine, in bacteriological investigations; Samuel Graham and S. Marcovitch, in entomology; A. W. Aamodt, in horticulture; G. R. Hoerner, in plant pathology; and A. L. Anderson, in veterinary science.

G. R. Bisbee has been appointed assistant plant pathologist, R. P. Ingram and Fern Pack, assistant seed analysts, and L. J. Hood, assistant editor, these dating from August 1.

Missouri University and Station.—J. O. Rankin has resigned as agricultural editor to become associate professor of agricultural economics at the Iowa College, and was succeeded November 1 by M. N. Beeler, agricultural editor at the University of Florida. A. R. Evans, instructor in farm crops, has resigned

to accept a position in the Office of Markets and Rural Organization of the U. S. Department of Agriculture.

Montana College and Station.—The chemical building was burned October 20. All the records, the chemistry library, and considerable apparatus were saved. D. S. Fox, Ph. D., has been appointed assistant professor of farm management.

New Jersey College and Station.—An international egg-laying and breeding contest is being conducted under the auspices of the stations at Vineland, N. J., beginning November 1 and continuing for three years. The contest is open to all poultrymen. One of the purposes in view is to throw light on some of the principles of breeding in fowls, especially of the inheritance of fecundity and other characteristics.

Work is being begun on a greenhouse for the department of plant pathology. S. A. Waksman, H. E. Carney, and Charles H. Richardson have resigned, the first named to accept a fellowship in the University of California, the second to become instructor in the biological sciences and agriculture in the Middletown Township High School, and the third to become assistant in biological chemistry at Columbia University. Recent appointments include Alvah Peterson, Ph. D., as instructor in entomology and assistant entomologist; Miss Nevada S. Evans. as assistant seed analyst; James W. Day, as assistant in agronomy; Joseph R. Neller, as research assistant in soils; and Thurlow C. Nelson in charge of oyster research.

North Carolina College and Station.—The Annual Farmers' Convention held at the college August 29–31, under the auspices of the college, station, and extension workers, was one of the most successful meetings of its kind yet held in the State. About 3,000 men and 2,000 women were in attendance. The special subject of the meeting was rural education, which was graphically presented by means of an exhibition in which several booths were grouped around a larger booth in one of the college buildings. The smaller booths represented the activities of the station and extension service, while the larger booth represented a consolidated or farm-life school. This exhibit attracted much attention from visitors.

E. A. Hodson, assistant professor of agronomy, has been given a year's leave of absence for graduate study, and his work is being taken by J. O. Ware, formerly agent for Columbus County. H. L. Joslyn, assistant professor of soils, has resigned to become superintendent of the Craven County Farm-life School and has been succeeded by T. H. Stafford. George H. Rea has been appointed specialist in bee keeping under a cooperative arrangement between the Bureau of Entomology of the U. S. Department of Agriculture and the extension service. D. G. Sullins has been appointed assistant in animal husbandry and dairying, J. H. Hall, assistant in plant breeding, vice Buxton White, resigned to become alumni secretary for the college, and C. C. Logan, extension specialist in soils.

Oregon College and Station.—The forestry building has been completed. A new swine feeding barn and laboratory is under construction and is expected to be ready for use in November.

Paul H. Crouter, a 1916 graduate, has been appointed superintendent of the Eastern Oregon substation at Union, and will have special charge of the cattle feeding experiments. D. E. Rickard, a member of the same class, has been appointed superintendent of the college live-stock farms, and Carey Lloyd Strome, a third member, has been selected as foreman of the seed crop farms. H. A. Schoth has accepted a position in vetch experiments in connection with the studies of the U. S. Department of Agriculture which are under way at the college.

Pennsylvania College and Station.—M. G. Kains, professor of horticulture and horticulturist, resigned October 1 and has been succeeded by Dr. S. W. Fletcher, formerly director of the Virginia Station. Earle L. Moffitt has been appointed assistant professor of farm management extension, effective November 13. A. B. Long, G. J. Kuhlman, and F. J. Holben have resigned as assistant chemists. R. H. Olmstead, a graduate of the college, has been appointed assistant in animal husbandry; H. Clyde Knandel, instructor in poultry husbandry extension; Albert F. Yeager and John S. Gardner, instructors in horticulture; and C. H. Hadley, jr., instructor in entomology extension.

Utah College and Station.—E. P. Taylor, professor of horticulture and horticulturist, has resigned to become director of agricultural extension at the University of Arizona. E. W. Stephens has been appointed assistant state leader of club work and will have charge of boys' clubs in the high schools. D. W. Pittman has accepted an appointment as instructor in agronomy and assistant agronomist.

Wisconsin University.—A. C. Baer, instructor in dairy husbandry, has resigned to become head of the dairy department of the Oklahoma College and Station.

Necrology.—Prof. Cleveland Abbe, widely known for his eminent services in meteorology in the Weather Bureau of the U. S. Department of Agriculture, died October 28 at the age of 78 years.

Professor Abbe was a native of New York City and educated at the College of the City of New York and Harvard University. He became assistant professor of engineering in the Michigan Agricultural College in 1859, and subsequently instructor in mathematics and astronomy at the University of Michigan. During the most of the Civil War he was a member of the U. S. Coast and Geodetic Survey, and from 1864 to 1866 a guest at the Nicholas Central Observatory near St. Petersburg, Russia.

On returning to this country he was appointed director of the Cincinnati Astronomical Observatory and in 1868 volunteered to make daily predictions of the weather for the benefit of the community. In September, 1869, he began the publication of a daily bulletin of weather probabilities based upon telegraphic reports from observers at a number of points. These forecasts soon attracted widespread attention.

A national bureau of storm warnings was established in 1870 under the direction of the Signal Service of the Army, and in the following year Professor Abbe became a scientific assistant in that work. During the long period of evolution of the U. S. Weather Bureau he was a prominent figure, editing the Monthly Weather Review in 1873 and again from 1892 to 1909, and the Bulletin of the Mount Weather Observatory during its entire period of publication. He was also the author of an extensive list of meteorological articles and several treatises.

Professor Abbe was a member of the National Academy of Sciences and of many other scientific organizations. He received in 1912 the Symons Memorial Gold Medal of the Royal Meteorological Society of England and recently the Marcellus Hartley Memorial Medal from the National Academy of Sciences, as well as the degree of LL. D. from the University of Michigan in 1888 and the University of Glasgow in 1896.

New Journals.—Better Business, a quarterly journal of agricultural and industrial cooperation, is being published by the staff of the Cooperative Reference Library of Dublin, Ireland. The initial number contains articles on the outlook for cooperators, the economics of continuous cropping, a translation of a report of the German Parliamentary Committee appointed to consider the ques-

tion of food supplies in war time, the development of the agricultural cooperative movement in England and Wales, reviews of the current literature on cooperation and related topics, etc.

Part 1 of Volume 1 of *Ectoparasites* has been issued and it is announced that succeeding parts will appear at irregular intervals. It is being edited by Dr. K. Jordan and N. Charles Rothschild. The initial part contains the following articles: On Some Siphonaptera Collected by W. Rückbeil in East Turkestan, by K. Jordan and N. C. Rothschild; Further Notes on *Siphonaptera fracticipita*, with Descriptions of New Genera and Species, by N. C. Rothschild; On Neopsylla and Some Allied Genera of Siphonaptera, by N. C. Rothschild; and Contribution to Our Knowledge of American Siphonaptera, by K. Jordan and N. C. Rothschild.

The State Plant Board of Florida has begun the publication of a *Quarterly Bulletin* devoted to applied entomology and plant pathology in general, with special reference to the prevention, control, and eradication of injurious insects and plant diseases in Florida. The initial number deals with citrus canker investigations.

The initial number of Archivos do Jardim Botanico do Rio Janeiro has recently been received. It contains three articles dealing with the flora of the region, and includes meteorological observations at the Garden in 1914.

Revista de la Sociedad de Medicina Veterinaria is being published by the Society of Veterinary Medicine of Buenos Aires. It is devoted mainly to original articles, bibliographical notes, the proceedings of the society, etc.

The Agricultural Journal is being published monthly by the department of agriculture of British Columbia, for the systematic dissemination of agricultural information.

Miscellaneous.—The Philippine Government has made available funds for the establishment of a permanent tobacco experiment station in the upper Cagayan Valley. The station is to be administered by the Bureau of Agriculture, with the Bureau of Internal Revenue and the College of Agriculture of the Philippines contributing advice and other assistance. D. B. Paguirigan and Alfonzo B. Cagurangan will be members of the staff.

At the last commencement of the University of the Philippines, the degree of Bachelor of Agriculture was conferred on nine candidates, that of B. S. in Agriculture on one candidate, and that of M. S. on two candidates.

A four-story annex to the Oka Agricultural Institute, Quebec, 160 by 63 feet, has been completed. This will be utilized mainly as a dormitory, but also contains classrooms for zootechny and field crops.

E. D. Ball, formerly director of the Utah Station, has been made state entomologist of Wisconsin, vice J. G. Saunders resigned to succeed H. A. Surface as economic zoologist of Pennsylvania.

According to a note in *Science*, C. B. Williams has been appointed to study the parasites of the sugar-cane frog-hopper in Trinidad.

# CONTENTS OF VOLUME 35, NO. 8.

Editorial notes:

The Washington Convention of the Association of American Agricultural Colleges and Experiment Stations  Recent work in agricultural science.  Notes	701 711 798
SUBJECT LIST OF ABSTRACTS.	
AGRICULTURAL CHEMISTRY—AGROTECHNY.	
The chemical nature of the "vitamins," I, Williams.  Hydrolysis of albuminous substances from seeds of Arachis hypogxa l'Aichnikov.  Influence of alkali and alkaline earth salts on casein, Robertson and Miyake  On the mechanism of oxidase action, Reed.  The ferments of pineapple juice, Fouqué.  The nature of the acid-soluble phosphorus of serum, Greenwald.  Factors influencing the lime and magnesia requirements of soils, MacIntire  Method for determination of immediate lime requirements of soils, MacIntire  Lime and magnesia in New Zealand soils, Aston  A rapid method for the estimation of calcium oxid in peat soils, Gortner  A rapid method for the estimation of fat in powders, Phillips.  The determination of sucrose in cane products by direct polarization, Muller.  The determination of essences in liqueurs, Rocques.  Manual for the essence industry, Walter.  Canning in glass by the cold pack method, Bell and Root.  Possibilities for the utilization of low-grade and surplus fruit, Caldwell.  Single-variety ciders and perry, 1913–14, Barker and Grove.	711 712 713 713 714 714 715 716 716 716 717 717 717

Page.

	Page.
The treatment of cider sickness, Grove	717
The relative value of cane and beet sugar for fermentation purposes, Grove	718
The fermentation of cane molasses; composition of rum, Kayser	718 718
Transformation of nitrogenous substances during curing of tobacco, Bernardini. Note on the detection of faulty sizing in high-grade papers, Sammet	718
Note on the detection of faulty sizing in high-grade papers, bammet	710
METEOROLOGY.	
Meteorology in relation to agriculture in Canada, Stupart and Mills	718
Meteorological observations, Eredia.  Frequency of low temperatures at Vercelli and its effect on rice, Marcarelli.	718
Frequency of low temperatures at Vercelli and its effect on rice, Marcarelli	718
Night frost in the East Indies, Van Bemmelen	719
The weather of Scotland in 1915, Watt. [The climate of Pavlovsk], Shipchinskii (Shipchinski)	719 719
[The climate of Paviovskj, Shipchillskii (Shipchillski)	110
SOILS—FERTILIZERS.	
Michigan's shifting sands: Their control and better utilization, Sanford	719
The weathering of podzol soils of middle Norrland, Tamm	720
Some problems of the study of forest soils, Borghesani	720
Chemical and biological notes on cherry orchard soils, Harvey and Hooper	720
Investigations on tobacco soils, Barker	720
Red soil, DeRegny	721 721
Notes on some west country soils, Gimingham	721
A new method for mechanical soil analysis, Odén	721
Judging soils on the basis of the hydrochloric acid extract, von Sigmond	721
The cause and nature of soil acidity, Truog	722
Preliminary studies on heated soils, Johnson	722
Changes in soils brought about by heating, Wilson	723
The occurrence of bacteria in frozen soil, Harder	723
Soil bacteria and phosphates, Hopkins and Whiting	723 724
Niter spots Stalder	724
Niter spots, Stalder	724
Red soils and phosphatic manuring, Arié	725
Electro-potash as a fertilizer, Rhodin.	726
Influence of calcium and magnesium compounds on plant growth, Wyatt	726
Sour soils and liming, Frear  Lime and its uses in agriculture, Harcourt	727 727
Liming and inoculating soils, Dorchester, Douglass, and Taff	727
The relation of sulphur to soil productivity Duley	728
The relation of sulphur to soil productivity, Duley  Can lithia be a constituent of plant food? Hahn  [Analyses of fertilizers and fertilizing materials], Rose and Wilson	728
[Analyses of fertilizers and fertilizing materials], Rose and Wilson	728
Commercial fertilizers, Jones, jr., et al	728
Report [of Ohio] on fertilizers and lime licensed during 1913	728
AGRICULTURAL BOTANY.	
Life cycles of the bacteria, Löhnis and Smith	728
Studies of Bacillus radicicala, Temple	729
Studies of Bacillus radicicola, Temple	729
The scope and relations of taxonomic botany, Hitchcock	730
Drug plants of North Dakota, Englehorn	730
Notes on Quamasia with a description of a new species, Piper	730
Branching and flowering habits of cacao and potashte, Cook.  The double stock, its history and behavior, Saunders.	730 730
Explanation of abnormally high records of doubles of stocks, Saunders	731
Relation of half-hoariness in Matthiola to glabrousness and hoariness, Saunders	731
Pollen sterility in relation to crossing, Gates and Goodspeed	731
On the germination of the pollen grains of apple and other fruit trees, Adams.	731
Vegetative succession under irrigation, Macbride	732
A climatic index to represent both moisture and temperature, Livingston	732 732
A living climatological instrument, Livingston and McLean.  The daily march of transpiring power, Trelease and Livingston	732
The transpiring power of plants as influenced by altitude and habitat, Shreve	732
4 0 5	

	Page.
Transpiration, root absorption, and water-absorbing capacity in Opuntia, Shreve	733
Measurement of the surface forces in soils, Shull	733
Tracheid dimensions in longleaf pine and Douglas fir, Gerry	734 734
Permeability and viscosity, Osterhout	734
The injurious effects of tarvia fumes on vegetation, Chivers	734
and any control of the first terms of the first ter	
FIELD CROPS.

## EXPERIMENT STATION RECORD.

Vol. 35.

DECEMBER, 1916.

No. 8.

Following the general policy adopted many years ago of meeting in alternate years in Washington, D. C., the Association of American Agricultural Colleges and Experiment Stations held its thirtieth annual convention in this city November 15–17. The selection of the nation's capital this year seemed especially appropriate, in view of the predominance in the program of questions of nation-wide significance, the important relationships developing with various branches of the Federal Government, and the plentiful evidences of the growing realization of the essential kinship and community of purpose of the institutions comprising the great Federal system of education and research for whose interests the association stands.

Official delegates were in attendance from every State in the Union except one, and from many institutions representatives were present for each of the four divisions of college, station, extension, and engineering activities. The total registration of delegates and visitors exceeded three hundred, and is believed to have eclipsed all previous records. This large attendance was doubtless due in part to the meetings of many related organizations and similar bodies.

Prior to the opening of the convention of the association itself, a four-day conference was held of the county agent leaders in extension work and the States Relations Service. The Society for the Promotion of Agricultural Science, the American Society of Agronomy, the National Potato Association, the National Association of State Universities, the American Association for the Advancement of Agricultural Teaching, the American Association of Farmers' Institute Workers, the Association of Feed Control Officials, and the Association of Official Agricultural Chemists also held sessions, and there was a conference of home economics teachers in the land-grant colleges under the auspices of the U. S. Bureau of Education. The annual meeting of the National Grange, this year celebrating its fiftieth anniversary, also brought to Washington a large number interested in agriculture, and a public meeting of this body, addressed

by President Wilson, tended further to focus attention in the city on matters pertaining to agriculture to an unusual degree.

The program of the Association of American Agricultural Colleges and Experiment Stations, however, was by no means restricted to agricultural lines. The interests of the association are, of course, considerably broader in scope, and this year in particular much emphasis was put upon what may be termed its nonagricultural phases. In the general sessions especially, aside from the addresses of the Secretary of Agriculture and the president of the association and the presentation and discussion of the reports of the standing committees, attention was centered quite largely on the proposed establishment by the Federal Government of engineering experiment stations, the development of military training in the land-grant colleges, and the best ways of conducting extension work in home economics and similar lines of interest to farm women. prominent position accorded these topics, coupled with those presented at the two sessions of the newly formed subsection of engineering, gave to the program an appearance of less emphasis on the distinctively agricultural phases of the work than has been usual in recent years.

This trend of the convention, however, in no sense betokened a diminution of interest in agricultural education and research. On the contrary, it may be questioned whether the realization of the outstanding importance of these phases, and especially the need of adequate and systematic provision for research, was ever more strongly in evidence. For example, it was the dominating note in the presidential address, given by Director C. E. Thorne, of the Ohio Station. upon the subject of Progress of Education and Research in Agriculture. Director Thorne reviewed the history of the land-grant colleges, especially in their relations to the experiment stations, and sounded a note of warning that the temptation to neglect the work of the stations in order to take care of the great pressure for educational work must be strongly resisted if permanent progress is to be made. As he pointed out, "science can not stand still. Every extension of the horizon of our knowledge only expands the boundary of the unknown, and makes yet more imperative the necessity for further research, and the institution which contents itself with present knowledge will soon find itself forgotten."

One interesting result of the discussion of topics seemingly little related to agriculture was the revelation of numerous ways in which they are in reality closely associated. For example, in the animated discussion of the proposed initiation of Federal aid to research in engineering, one of the principal arguments advanced for the loca-

tion of the prospective stations at the land-grant institutions was the successful maintenance of corresponding stations for experimentation in agriculture. The belief was widely expressed that agriculture and the mechanic arts are not only vitally related, with many points of contact, but possess plentiful opportunities for mutual service.

Thus, Dean A. A. Potter of the Kansas College said, "The location of the proposed experiment stations at land-grant institutions will result in close cooperation between the engineering and the agricultural experiment stations. Such cooperation will prove beneficial to modern agriculture and will also result in the utilization of waste materials from the farms. The increased use of farm machinery and of farm motors on modern farms merits much engineering investigative work of direct benefit to the agricultural industry. Other engineering investigations, such as road building, rural architecture, drainage, and irrigation, can best be carried on at land-grant institutions, where the engineering experimenters can secure valuable aid from their colleagues in the agricultural experiment stations."

Even the authorization of the reserve officers' training corps in the land-grant colleges, under the provisions of the National Defense Act, was shown to have a bearing on the preparation of teachers and investigators in agriculture. The paper of Dean Edward Orton, jr., of the Ohio State University, pointed out that the establishment of these units will involve considerable reconstruction of courses, and he maintained that the theoretical military training prescribed can, in many cases, be obtained only by a replacement of other studies—cultural, scientific, or technical. While it is expected that the reserve officers will be developed more largely from students in engineering than in agriculture, there will none the less be some reconstruction of agricultural courses, and the problem will thus be presented of insuring that the fundamentals of a sound scientific and technical training be carefully conserved.

The relationship of home economics and agriculture have long been recognized, yet it remained for this convention to bring out the extent to which the comparatively new campaign for the betterment of the country home is going forward and to draw attention to some of its special problems. Practically an entire day was given to the subject, most of one morning's general session and the afternoon meeting of the section on extension work.

The general session devoted to home economics was opened with the report of the bibliographer, Dr. A. C. True of the States Relations Service, which dealt with published sources of information about farm women. This report was very suggestive in several ways. It included less than a dozen books, articles, and bulletins dealing exclusively with the subject, with about 150 other references to various phases. In assembling the material an extreme meagerness of investigational data, coupled with the frequent but superficial treatment of the subject in books on country life, rural education, and economy, a tendency to give much space to the experiences of individual country women, and the popularity of the farm woman as a subject of discussion among organizations representing a surprising variety of interests, were among the characteristics discovered.

An illuminating idea of the field still to be traversed by home economics writers was also afforded. In the words of the report, "problems have been worked out in individual cases and the results applied in practice, but as yet the economic, sociological, and psychological principles underlying this work have not been analyzed and formulated. Standards, such as are used in farm-management work, have not been worked out by surveys; accumulated practical experience has not been summed up and presented in a systematic way for the guidance of others."

This report should prove extremely helpful to home economics workers. As the quotation indicates, there is great need for fundamental studies in home economics analogous to the experimentation in agriculture. Yet in spite of the large amount of time allotted the subject on the program, this phase otherwise received only incidental mention, attention being concentrated almost wholly on the extension side of the work. A symposium was given before the general session on organization and administration under the Smith-Lever Act as related to the home economics departments and the farm home, while the sectional program dealt with home economics extension in its relations to women's work in the home, rural engineering and architecture, and rural health and personal hygiene, and a discussion of the function of the woman extension worker. These papers revealed in a most interesting way the many channels which are being developed to reach the farm home. It seems clear, however, that the need and opportunities for research would be an especially appropriate topic for future discussion in the new subsection of home economics, the establishment of which was authorized by the college section.

Extension problems in agriculture likewise attracted much attention. The standing committee on extension organization and policy submitted a carefully prepared report discussing the relationships between the colleges and the U. S. Department of Agriculture. The section of extension work considered two main topics, the use of the written project system and the holding of National conferences on extension projects. Extension relationships were also first among the topics discussed by Secretary Houston in his address before the as-

sociation, in which he expressed his appreciation of the spirit of cooperation evinced on the part of the States in the coordination of the agricultural activities of the Nation. Already, he stated, in spite of the difficulties inherent in inaugurating so large and complex an enterprise, the States are cooperating with the Federal Government far beyond the requirements of the law.

College instruction in agriculture was discussed from several points of view. The report of the standing committee on instruction in agriculture dealt with the question of college credit for high-school agriculture. This included a study of existing conditions, by Mr. D. J. Crosby, which indicated that agriculture is now accepted as an entrance subject in forty-four of the forty-eight States, but that only one institution allows advanced credit. It was found that agriculture is now taught in 19 per cent of the high schools of the country, and the committee considered this a factor which might well be taken into account in college instruction to a greater degree. Certain fundamental principles of agriculture, it pointed out, might be taught as effectively in the high schools as in the freshman class, or even better if the college instruction is delegated to fellows and assistants of limited years and experience.

Some obstacles, however, were recognized to the acceptance of high-school agriculture, especially the wide variation in the grade of work accomplished. Care is needed in the selection of textbooks and apparatus and the outlining of courses, and it was suggested that the colleges might here render a useful service. In twenty-eight States there is no systematic supervision of high-school instruction in agriculture. In some States the college and the State Board of Education cooperate, but it was believed that the efforts of the colleges in this field should be suggestive rather than arbitrary, and should scrupulously avoid the appearance of domination.

Methods of Improvement in Teaching College Agriculture were discussed by Dean W. W. Charters of the School of Education of the University of Missouri. Dean Charters pointed out that the important thing in education is not apparatus or buildings or equipment, but the classroom intercourse of teacher and student. He believed that the present teaching of agriculture is very uneven in quality. One difficulty is that the results of teaching are less tangible than those of research and therefore easy to judge in a comparative way. The code of professional ethics which bars instructors of equal rank from the classrooms of others also hinders improvements and obscures the merits of efficient teachers. More attention to the formulation and application of pedagogical principles of agricultural instruction was earnestly advocated. It is of interest to note that very

similar views were expressed in the section on engineering as regards instruction in that subject, and that close cooperation with schools of education was a suggested remedy.

Another way to increase efficiency in the colleges was proposed by President Waters, of Kansas, in a paper favoring an increase in the length of the college year. President Waters pointed out that under the present plan, the bulk of the enormous educational investment is idle almost one-third of the year, and he also maintained that this involves a great loss of time to the student. He summarized tests which indicated that the objection to summer study in warm climates is not valid, these tests indicating that mental efficiency, instead of being impaired by hot weather, steadily increases during the summer to a maximum in October or early November, and then declines to a minimum in midwinter. The ever-growing attendance at summer schools offering college credit was also cited as evidence that the customary vacation is longer than necessary, and that many students welcome the opportunity to hasten the completion of the period of preparation for their life work.

The employment of graduate students as research assistants in the station formed the subject of a joint meeting of the college and station sections. Director J. G. Lipman described the system carried on at the New Jersey Stations, where nine such assistants are now at work, and claimed advantages to both the station and the student. Graduate students as a class have been found to possess marked mental keenness and zest, and while not available for the working out of comprehensive projects can frequently be entrusted with certain important details, such as the compilation of bibliographies, the recording of results, and the tabulation of data, and even the handling of some minor problems like the study of a single soil organism or the effect of a method of treatment. In the discussion which followed the successful employment of graduate assistants was reported from several other stations.

A paper by Prof. L. R. Jones, of the University of Wisconsin, took up the same matter from the standpoint of the graduate student, considering especially some of the difficulties which might be encountered. Among these he mentioned the possibility of exploitation, the danger of attracting the weaker graduates, and the desirability of minimizing the risk of inbreeding. He maintained that a student ought not to be allowed to continue on such a basis year after year, especially at the same institution, but that even if it involved some temporary inconvenience to the station, he should, whenever his own well-being demanded it, be encouraged to "migrate" elsewhere. The fundamental consideration, therefore, in the

employment of this class of assistants should be their ultimate development as well prepared investigators.

The responsibility of the stations to present their results in a form available for popular use was emphasized in a paper by Director R. L. Watts, of Pennsylvania, entitled Shaping Results of Experiment Station Work for Extension Uses. This paper took the ground that the experimenter himself, who knows the results better than anyone else, should, as a rule, serve as the translator of technical work into popular form. He should, therefore, make a study of methods of presentation of results. Some of the principles to be observed were explained and illustrated by means of charts comparing the effectiveness of tables, graphs, maps, and the like. The use in the popular presentation of results of massive tables, poor photographs, complicated charts, and graphs of technical appearance was deprecated, while skillfully designed charts and graphs, good photographs, even if of small size, and condensed tables may be very effective.

Some general aspects of station publications were brought out in the ensuing discussion. The opinion was expressed that many bulletins need not be made so technical as to be beyond the comprehension of the farmer, and that others might be published in more than one form. There was general agreement as to a real danger of an overshadowing of the station by cutting off the staff from direct communication with the farming public. While it is true that the time of the research worker must be husbanded, he is none the less entitled to present his results directly and in his own way. Above all he should be safeguarded against any tendency by others to "play up" special features.

The important subject of the relations of the stations to regulatory work, concerning which the standing committee on experiment station organization and policy had submitted a report at the 1915 convention, had originally been assigned to the late Director Kastle, of Kentucky, and the paper presented in his stead by Dean A. F. Woods, of Minnesota, embodied some material collected by him. A considerable amount of data as to existing methods of handling regulatory work in the various States was summarized, but as an indicator of the desirable future policy the discussion as a whole was far from exhaustive.

There was considerable support of the view that with well managed state boards of agriculture, safeguarded by civil service regulations, the stations might well be relieved of police duties alien to their real purpose as research institutions, and that if the stations were to be expected to carry on such work they should organize it as independently as possible from their other work. It was some-

what unfortunate, however, that the lateness of the hour at which this topic was reached on the program tended to prevent a more complete discussion, and its reassignment at some subsequent meeting would seem to be amply justified.

A discussion on the Correlation of the Work of Experiment Stations in Regions with Similar Conditions was opened by Director J. C. Kendall, of New Hampshire, and participated in quite generally. Many possibilities of such correlation were pointed out, and instances cited of work already in progress. Some apprehension was expressed lest it result in an abridgment of the freedom of the individual investigator, and emphasis was laid on the individual factor in research. Others expressed the conviction that, at least in the simpler forms of inquiry, an understanding of what others in the same field are attempting might frequently enable individual workers or stations to coordinate and readjust their work to advantage. Thus, while certain types of duplication of work are not harmful and others may be beneficial as a corroboration of results, there are instances where mere repetition does not strengthen, as was intimated in the report of progress of the standing committee of the association on projects and correlation of research.

The meetings of the station section were unusually well attended, and the discussions as a whole were participated in by a large number of those present. The program was originally arranged for a single afternoon session, but in its consideration most of a second afternoon was eventually utilized.

The business of the association itself centered largely around the questions of the engineering experiment stations and the development of courses in military training. On the first of these propositions, the association reaffirmed its belief in the advantages of organizing enginering experiment stations, and declared that Federal aid for such stations should follow the lines of the Morrill Act and its supplementary legislation, irrespective of local conditions. The executive committee was empowered to represent the association in conference with other bodies interested in the formulation of such legislation.

The association expressed its interest and appreciation of the advantages of the proposed training corps sections of the National Defense Act, and manifested its desire to cooperate with the War Department in its practical application. The measure was discussed in detail by members of the association and Maj. Andrew Moses, of the War Department, in one of the general sessions, and provision

was also made for special conferences of those interested at that Department.

The report of the standing committee on graduate study described the work at the 1916 session at the Massachusetts Agricultural College and discussed the steadily decreasing attendance at these sessions. The decline was attributed in part to the large amount of summer work now being required of many members of college faculties, but even more directly to the increased facilities now available for systematic graduate study in agriculture and the fact that this instruction could be recognized by academic credit. During the past year 25 institutions registered at least 6 graduate students in agriculture, and the total was not far from 1,000. The committee recommended that, in view of these changing conditions, the 1918 session of the school be postponed for one year, and that the association consider at its next meeting the general question of the continuance of the school. This recommendation was accepted by the association.

Resolutions presented by a special committee on the death of Dr. J. H. Kastle were adopted by the association. These resolutions included a fitting tribute to Dr. Kastle, stating that in his death the association "has lost a valued member, the science of chemistry one of its most able investigators and teachers, agriculture an exponent of unusual breadth of view, and the scientific world in general a worker conspicuous for his tireless energy in the prosecution of its work and a master in the presentation of the results of his labor."

The next meeting of the association will probably be held in Massachusetts in October, 1917. An invitation was received to hold the sessions in Springfield, Massachusetts, with a one-day program at Amherst in connection with the celebration of the fiftieth anniversary of the opening of the Massachusetts Agricultural College. A vote of preference was given for this procedure, subject to alterations if deemed advisable by the executive committee.

The election of officers resulted in the selection of President K. L. Butterfield, of Massachusetts, as president; President C. A. Lory, of Colorado, President Brown Ayres, of Tennessee, Dean J. L. Coulter, of West Virginia, President C. A. Duniway, of Wyoming, and President W. B. Bizzell, of Texas, vice presidents; and the reelection of the previous secretary-treasurer and bibliographer. The membership of the various committees underwent few changes. President R. A. Pearson, of Iowa, succeeded President Ayres as a member of the executive committee, and Dean E. Davenport, of Illinois, replaced President Howard Edwards, of Rhode Island, as a member of the committee on graduate study.

The section officers included, in the college section, President C. C. Thach, of Alabama, chairman, and Dean A. F. Woods, of

Minnesota, secretary; in the station section, Dean R. S. Shaw, of Michigan, chairman, Dean W. M. Jardine, of Kansas, secretary, and Mr. W. H. Beal, of the States Relations Service, recording secretary; in the extension work section, Mr. R. K. Bliss, of Iowa, chairman, Mr. C. R. Titlow, of West Virginia, secretary, and Mr. C. B. Smith, of the States Relations Service, recording secretary; in the engineering section, President W. H. S. Demarest, of New Jersey, chairman, and Dean A. A. Potter, of Kansas, secretary; and in the home economics section, Miss Josephine T. Berry, of Minnesota, chairman, and Miss Helen Knowlton, of New Hampshire, secretary.

The 1916 convention was thus an interesting and important gathering, and though its dominant interests were not directly agricultural it was of much service in this direction. It emphasized, as perhaps no previous meeting has done, the essential solidarity of the component institutions, and revealed opportunities still existing for even more complete cooperation and mutual helpfulness.

# RECENT WORK IN AGRICULTURAL SCIENCE.

## AGRICULTURAL CHEMISTRY-AGROTECHNY.

The chemical nature of the "vitamins."-I, Antineuritic properties of the hydroxypyridines, R. R. Williams (Jour. Biol. Chem., 25 (1916), No. 3, pp. 437-445).—The author has prepared the following pyridine derivatives and tested their therapeutic action on polyneuritic pigeons by intramuscular injection of doses of from 1 to 10 mg.: Nicotinic, cinchomeric, quinolinic, 6-hydroxynicotinic and citrazinic acids, α-hydroxypyridine, glutazin, 2-, 4-, 6-tri-hydroxypyridine and its anhydrid, and 2-, 3-, 4-trihydroxypyridine and the so-called tetrahydroxypyridine.

Of these substances definite evidence of curative power was noted only in the case of a-hydroxy-, 2-, 4-, 6-trihydroxy-, and 2-, 3-, 4-trihydroxypyridine. The remainder of the series showed no effect whatever, although it is deemed that such negative evidence in the case of any hydroxy derivatives can not be regarded as conclusive. It was noted that all the cures obtained were of those pigeons which were treated with freshly prepared materials, while those treated with the same preparations a few days or weeks later invariably received no benefit. The substances were evidently changed in some manner so as to lose their curative power, although no deterioration was evident. The existence of a tautomerism in the hydroxypyridines suggested itself as being of some interest in this connection.

Following this suggestion it was found that a granular and a crystalline needle form of a-hydroxypyridine could be prepared, both of which melted sharply at from 106 to 107° C. After proper purification by remelting, keeping well above the melting-point temperature for some time, and then allowing to cool slowly, the mass was found to consist largely of needles. By recrystallization from benzene with ligroin it was sometimes possible to obtain the needles free from any granular crystals. On allowing the solid needle form to stand for a few days in an open vessel or cork-stoppered bottle it was observed that the crystals had undergone a change. The original clear and sharply defined needles were marked by transverse lines of cleavage. The rate of the change was variable but apparently depended on the amount of moisture in the atmosphere surrounding the crystals. Neither of these forms was found to absorb appreciable amounts of bromin instantaneously when titrated in the cold with alcoholic bromin, so that neither form could have been the hydroxy or enol form. On dissolving either form in an excess of alcoholic NaOH of known strength an instantaneous absorption of bromin in excess of that required by the alkali occurred.

"It appears that there exist not two but three isomeric forms of a-hydroxypyridine... By simple means we may cause any desired form to predominate and may pass through the cycle repeatedly. Each exists in equilibrium with at least one other in relative quantities depending on conditions. We shall understand their relationships fully only after finding a method for determining each of the three forms quantitatively under varying conditions. At present we can measure only the amount of enol." The results from tests made on pigeons with these forms of  $\alpha$ -hydroxy-pyridine in general approximated very closely those obtained with hydrolyzed extract of rice polishings, both in rapidity and completeness of action of the paralytic symptoms. Boiling temperature destroyed the curative power of the needle form, and in solutions more than five or six days old it was no longer detectable.

The granular form obtained by prolonged standing of the needles was tested on a number of birds in various quantities and under various conditions, but in no case was there the slightest evidence of any benefit. "This absolute lack of curative properties is striking and suggestive. If the isomeric forms exist in equilibrium and there is fairly rapid transformation in any direction, one would suppose that the granular form would, when injected into the body, rapidly convert itself into the curative form as the latter was removed from solution by absorption in the tissues or fluids requiring it. That such is not the case suggests strongly that the pathological conditions of polyneuritis are not due to a deficiency of a substance per se, but to a lack of a certain type of potential energy which only certain substances can supply. In other words ... it is the potentiality of isomeric change that produces the desired result. In this connection it is interesting to note that many purin and pyrimidin derivatives, some of which Funk [E. S. R., 27, p. 868; 29, p. 664] has reported to be partially curative for polyneuritis are also theoretically capable of a similar isomerism. That these substances are to a greater or less degree enolketo tautomers is strongly indicated, by well-known reactions of uric acid for example. The existence of a third isomer is not excluded by theoretical considerations, but lacks the support of any considerable experimental evidence."

It is indicated that the antineuritic properties of these substances "suggest that an isomerism is at least partially responsible for the instability of vitamins in foodstuffs, and that the antineuritic property may be inherent in the potentiality of this type of isomerism. We may not conclude that vitamins are necessarily hydroxypyridines, since a similar isomerism may exist in substances containing other heterocyclic nitrogenous nuclei which are known to occur widely as constituents of animal tissue."

Separation and hydrolysis of albuminous substances from the seeds of Arachis hypogæa, I. S. ÎAichnikov (Jainschnikow) (Iz Rezul't. Veget. Opytov Lab. Rabot (Rec. Trav. Lab. Agron.), 9 (1913), pp. 378-385).—Proteins from the seeds of A. hypogæa were extracted by means of water, 70 per cent alcohol, a 10 per cent solution of sodium chlorid, and a 0.25 per cent solution of potassium hydroxid. The total amount of nitrogen in the seeds was found to be 9.1 per cent, of which as much as 8.74 per cent occurred as albuminous substance, including albumin, glutin, and globulin. Glutin and globulin were hydrolyzed with the subsequent separation of histidin, arginin, and lysin. The work and the methods employed are described in detail.

The influence of alkali and alkaline earth salts upon the rate of solution of casein by sodium hydroxid, T. B. ROBERTSON and K. MIYAKE (Jour. Biol. Chem., 25 (1916), No. 3, pp. 351-361).—Analytical data submitted show that "the presence of alkali or alkaline earth chlorids in the sodium hydroxid solutions employed as solvent . . . decreases the rate of solution of casein by dilute sodium hydroxid. The retardation increases with the concentration of salt employed. The alkaline earth chlorids in 5/1,000-normal concentration retard the rate of solution of casein approximately to the same extent as 100 times this concentration of a chlorid of an alkali." The amount of casein dissolved (X) is expressed by the formula  $X=Kt^m$ ; K and M being constants and M expressing the time. The constants depend on the concentration and kind of alkaline solution employed as solvent.

On the mechanism of oxidase action, G. B. Reed (Bot. Gaz., 62 (1916), No. 1, pp. 53-64, figs. 4).—In connection with certain experiments the author has observed that different samples of colloidal platinum and silver (prepared by passing a direct current between two electrodes of the metal under water) behaved differently toward solutions of gum guaiac. The guaiac was in some cases oxidized directly, while in others only after the addition of a peroxid. This phenomenon suggested that samples of colloidal metal might contain different proportions of oxygen, and further that the amount might be varied by suitable treatment. The following experiments which prove the supposition to be correct are reported:

A large platinum crucible with a surface of about 150 sq. cm. (about 23.25 sq. in.) was platinized in the ordinary manner, by making it a cathode in a solution containing 2 gm. platinum chlorid and 0.16 gm. lead acetate in 60 cc, water, until the surface was uniformly coated with a black deposit of colloidal metal. It was then subjected to active hydrogen by making it a cathode in a dilute solution of hydrochloric acid. The crucible thus treated when placed in a solution of gum gualac free from peroxid or any solution of potassium iodid produced no oxidation. After subjecting the colloidal metal to active oxygen, however, it produced rapid oxidation when placed in either of these solutions. Although the reaction took place rapidly it was observed that only a very small amount of material was oxidized.

To determine whether only sufficient oxygen for a limited oxidation was taken up by the platinum, the oxidation of formaldehyde to formic acid, which is catalyzed by platinum black and which can be accurately and conveniently measured, was undertaken. About 80 cc. of a solution containing 5/100-molar NaOH and approximately 3/10-molar formaldehyde was placed in an open beaker in a water bath maintained at a constant temperature of 30° C. The platinum crucible was freshly platinized, exposed to active oxygen for five minutes, and after being thoroughly washed introduced into the solution of formaldehyde. The mixture was kept thoroughly stirred throughout the experiment, and at frequent intervals 2 cc. portions were removed and titrated with 5/100-molar hydrochloric acid. The amount of NaOH neutralized by the formic acid generated in the reaction was thus obtained. The results are expressed graphically and support the supposition noted above.

Other experiments in a study of the mechanism of the oxidation of formaldehyde to formic acid with platinum as a catalyst are reported. The results show that in the oxidation of formaldehyde by hydrogen peroxid in the presence of platinum black the platinum combines with oxygen from the hydrogen peroxid as it combined with oxygen when subjected to anodic oxidation. This compound of platinum then gives up its oxygen to the formaldehyde, producing formic acid.

From the results in general it may be concluded that "when colloidal platinum is introduced into a mixture of hydrogen peroxid and an oxidizable substance the platinum takes up oxygen from the peroxid, thereby forming a more efficient oxidizing agent than the original hydrogen peroxid. The catalytic action of the platinum in this case, that is its peroxidase action, therefore depends upon its aptitude for forming unstable oxygen compounds when it is in contact with hydrogen peroxid."

Similar work with plant material is in progress.

The ferments of pineapple juice, H. Fouqué (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 12, pp. 433-435).—In the study reported the pineapple juice was expressed as aseptically as possible, received in sterile flasks, and allowed to ferment, some samples under anaerobic and others under aerobic

conditions. When the fermentation was complete nutrient gelatin was inoculated with the various fermented juices.

From the aerobic fermentations three organisms, which have been designated as a, b, and c, were isolated, and from the anaerobic fermentation the organisms a and c and another predominating form (d). In further experiments sterilized pineapple juice was inoculated with the various organisms isolated, and the speed and character of the fermentations observed.

The cultural and morphological characteristics of the organism d are described. Both it and the organism b belong to the genus Saccharomyces. The organisms a and c seem to be intermediate between the Mycoderma and the Torula.

The nature of the acid-soluble phosphorus of serum, I. GREENWALD (Jour. Biol. Chem., 25 (1916), No. 3, pp. 431-435).—Experimental data submitted indicate that the phosphorus compounds of serum consist almost exclusively of phospholipins and inorganic phosphate. The presence of a form which is insoluble in dilute acids but is not precipitated by magnesia mixture or molybdate solution was also indicated. This latter does not dialyze readily from the serum.

Factors influencing the lime and magnesia requirements of soils. A method for the determination of the immediate lime requirements, W. H. MacIntire (*Tennessee Sta. Bul. 115 (1916)*, pp. 5-48, figs. 2).—A restatement and discussion of some of the data previously reported (E. S. R., 31, p. 815), with the addition of new material.

Analytical results secured in the determination of residual carbonates demonstrate the existence of a long-continued reaction between soils and carbonates. Such data emphasize the necessity of defining more specifically the term "lime requirement," and appear to necessitate a differentiation between temporary or immediate lime requirement and the continued propensity of a soil to decompose calcium carbonate when it continues in contact with excess carbonates. Whether the lime requirement of a soil should be considered as its maximum coefficient of calcium carbonate decomposition under laboratory conditions in a given time, or whether it should be considered as the amount of lime essential to maximum crop response for a definite period after treatment is an undecided question. "The feasible procedure would be to determine a method which would affect the maximum decomposition of CaCO₃ by its contact with the acid-reacting soil constituents under well-controlled laboratory conditions, and then, if possible, to establish a relationship between this maximum decomposition and practice."

Results from laboratory experiments on the decomposition of earth carbonates by sterile alkaline soils agree with the observations of Morse and Curry (E. S. R., 21, p. 713). Silicic acid was found to be a considerably stronger acid in its action on carbonates than has been hitherto supposed. "Where lime is added in amounts sufficient both to meet lime requirements and to insure an excess of carbonate, which would be the more subject to action of carbonated water, any calcium silicate resulting from treatment would probably remain largely as such. However, in presence of carbonated water the lime-silica reaction is readily reversed." Further observations show that the reaction between magnesium carbonate and silica and siliceous compounds is more extensive than that between these substances and calcium carbonate. The reversal of the magnesia-silica reaction through hydrolysis in the presence of carbon dioxid in solution was found to be correspondingly more difficult than that of the lime-silica compounds.

Further data presented demonstrate "that after the elimination of biological influences and the removal of organic and inorganic colloidal matter, we secure

a continued decomposition of earthy carbonates by alkaline soils under moist contact conditions at normal temperatures. This decomposition is shown to be very appreciable in the absence of any hydrated silicates."

The reaction of soil and calcium carbonate thrown out of carbonated water solution by agitation and suction and the effect of the period of contact of soil and  $CaH_2(CO_3)_2$  solution before evaporation was also studied. The data obtained demonstrate that a great difference in time of contact in the laboratory affects in some degree the extent of the reaction between the carbonate and the soils.

It is indicated that "MgCO₃ will satisfy a soil's requirement for lime, but that the satisfying of a soil's requirement for lime by long continued contact with CaCO₃ does not inhibit the excessive decomposition of added MgCO₃ under laboratory treatment. Not only is this true of normal calcareous soils, but it is also true of soils which have been ignited with an excess of CaCO₅."

"The combined presence of calcium, sodium, and potassium carbonates is not necessarily inhibitory of the decomposition of the precipitated carbonate of magnesium."

A procedure for the determination of the immediate lime requirement of soils, in which a suitable sample of soil is evaporated with calcium carbonate solution and the excess carbon dioxid then determined according to the procedure previously noted (E. S. R., 30, p. 808), is described in detail, together with the procedure for preparing the calcium carbonate stock solution and a pressure container for the same. A convenient form of carbon dioxid generator is also described.

From a comparison of the proposed method with the procedure of Hutchinson and MacLennan (E. S. R., 32, p. 609), it is indicated that "not only does the Hutchinson-MacLennan method fail to produce the decompositions equivalent to those effected by the Veitch [E. S. R., 14, p. 418] or the proposed method, but the carbonated water solvent depresses the reaction and gives less carbonate decomposition than is effected by agitation with CaCO₃ in CO₂-free water for the same period at room temperature."

It is deemed that the conditions of the procedure described effect the complete satisfying of the temporary lime requirement of soils, and it is intended to supply a simple means which will permit the satisfying of the maximum immediate lime requirement of acid silicates and silicic acid, the principal causes of lime requirement in rock-derived soils.

The relation between laboratory and field lime requirements and the occurrence of soil acidity in field and laboratory experiments are briefly described.

A method for the determination of the immediate lime requirements of soils, W. H. MacIntie (Jour. Indus. and Engin. Chem., 7 (1915), No. 10, pp. 864-867, figs. 2).—The method described, together with the procedure for preparing and standardizing the calcium carbonate solution, a pressure container for the same, and a modified form of carbon dioxid generator are noted above.

Lime and magnesia in New Zealand soils, B. C. Aston (Jour. Agr. [New Zeal.], 12 (1916), No. 1, pp. 47-54).—Analyses of 366 samples of New Zealand soil showing the calcium and magnesium oxid contents as extracted by hydrochloric acid and by 1 per cent citric acid are reported, the results of which indicate that the lime content of these soils is relatively low. "When soils which are known to be sterile owing to the excess of magnesia, when the magnesia is present in quantities ten times as great as the lime, both weak and strong solvents indicate that the magnesia is in excess...

"Soil which will grow forest, although showing a greater amount of magnesia than lime by the hydrochloric-acid method, shows a greater amount of lime than magnesia by the 1 per cent citric-acid method of extraction, whereas

the soil which will only grow scrub shows more magnesia than lime by both methods, as, similarly, does the soil which will not grow anything." It is indicated that "it may be ultimately found . . . that the 1 per cent citric-acid method . . . may prove a means of diagnosing an injurious excess of magnesia in soils,"

A rapid method for the estimation of calcium oxid in peat soils, R. A. GORTNER (Soil Sci., 1 (1916), No. 5, pp. 505-508).—In connection with some work on peat soils at the Minnesota Experiment Station the author devised the following procedure for the determination of calcium in peat:

Five gm. of peat is incinerated in a quartz dish, the ash digested with aqua regia, evaporated to dryness to dehydrate the silica, the residue taken up with dilute acid, filtered into a 500 cc. flask, and made to volume. To 100 cc. of this solution enough ammonia is added to make the liquid smell strongly and to precipitate the iron and aluminum. The liquid is brought to a boil, and while boiling 10 cc. of a saturated solution of ammonium oxalate is added. The calcium oxalate is thus precipitated over the surface of the iron hydroxid, making the latter more or less granular, and greatly aiding filtration and washing. The boiling is cautiously continued for a few minutes and the solution allowed to cool.

After at least three hours, or preferably overnight, the solution is filtered and well washed with warm water. When the precipitate is completely washed, the beaker in which the precipitation was made is placed under the funnel, a hole punched in the filter paper, and the precipitate washed into the beaker with a stream of warm water. The filter is then well washed with a hot 1.5 per cent sulphuric acid solution, 10 cc. of concentrated sulphuric acid is added to the washings, the solution brought nearly to a boil, and the oxalate titrated with a standard potassium permanganate solution of such strength that each cubic centimeter is equivalent to 0.001 gm. of calcium oxid.

Analytical data submitted indicate the accuracy of the procedure. The method is not applicable to mineral soils, the results being consistently high.

A rapid method for the estimation of fat in powders, S. B. PHILLIPS (Analyst, 41 (1916), No. 482, pp. 122, 123, fig. 1).—The author describes a specially devised apparatus for use in the estimation of fat in powders, using trichlorethylene as a solvent. The method is similar in principle to the procedure described by Neumann (E. S. R., 26, p. 507) and is claimed to yield excellent results.

The determination of sucrose in cane products by direct polarization, using a new method for the destruction of the reducing sugars, C. MULLER (Internat. Sugar Jour., 18 (1916), No. 210, pp. 274, 275).—For the destruction of reducing sugars in the determination of sucrose in cane products by direct polarization the author describes the following procedure:

A reagent is prepared by dissolving 25 gm. of Rochelle salt and 32 gm. of sodium hydroxid in 400 cc. of distilled water. To this, after heating slightly to effect solution, is added 11 gm. of bismuth subnitrate, heating being continued to dissolve the salt, after which the solution is cooled, made up to 500 cc., mixed, and filtered.

To use this reagent for the destruction of reducing sugars in the case of a cane molasses 20 gm. is diluted with 40 cc. of boiling water, 10 cc. portions of this dilution being poured on the weighed sample at a time, or 50 cc. of a solution containing 20 gm. of the molasses may be used. The liquid is placed in a 300 cc. flask, 15 cc. of the bismuth reagent added, and the mixture heated in a boiling water bath for 15 minutes. The liquid is then cooled, 150 cc. of cold water and the equivalent of 60 cc. of basic lead acetate of the density of

36° B. added, the volume made up to 300 cc., and the liquid mixed and filtered. It is now polarized by introducing 100 cc. into a 100-110 cc. flask, adding 5 cc. of acetic acid and sufficient water to reach the upper mark, treating with 2 gm. of special dry decolorizing carbon, mixing, and filtering, the observation being made in the 400 mm, tube.

It is indicated that the method is simple, rapid, and certain. "It is . . . applicable to all cane-sugar factory products, but not to special products such as those of the beet-sugar factory containing glutamic and aspartic substances, the optical activity of which is not destroyed by the bismuth reagent."

The determination of essences in liqueurs, X. Rocques (Ann. Falsif., 9 (1916), No. 90-91, pp. 127-134).—These pages report the findings of the committee appointed to investigate methods for the determination of volatile oils in liqueurs, necessitated by the recent legislation in France which ruled that not more than 0.5 gm. of oil be used in 1 liter of liqueur.

The volumetric method of Ronnet and the gravimetric method of Muttelet, both previously noted (E. S. R., 35, p. 111), are recommended as being satisfactory for the control of the purity of these products. The methods are described in detail and comparative analytical data submitted.

Manual for the essence industry, E. Walter (New York: John Wiley & Sons, Inc., 1916, pp. III+427, figs. 37).—This volume describes the most modern methods for preparing all kinds of-essences for liquors, brandies, liqueurs, and all alcoholic drinks, fruit juices, fruit wines, and mineral waters, together with many other valuable formulas. Other topics considered are the taste and the transfer of flavor to foods and beverages; the raw materials yielding the different tastes; confectionery, bakery, and culinary essences; coloring matters for foods and drinks; and cosmetic essences (perfumery, cosmetics, and soap perfumes). A chapter on laboratory practice, consisting of general manufacturing and analytical methods, is included, and a complete subject index is appended.

Canning in glass by the cold pack method, BAB BELL and ADDIE D. ROOT (Univ. Missouri Col. Agr. Ext. Serv. Circ. 9 (1916), pp. 12, figs. 6).—This circular briefly discusses the subject under the following heads: Why fruits and vegetables spoil; types of canners which may be used; and jars, tops, and rubbers. Directions for canning various fruits and vegetables are outlined in detail.

Some possibilities for the utilization of low-grade and surplus fruit, J. S. CALDWELL (Washington Sta. Popular Bul. 102 (1916), pp. 4).—This briefly summarizes the material previously noted (E. S. R., 35, p. 418).

Single-variety ciders and perry, 1913-14, B. T. P. BARKER and O. GROVE (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1914, pp. 11-21).—These pages record analytical data on a number of single-variety ciders and a perry made from fruit collected during the season of 1913, together with remarks on the general character of the products. The analytical data include specific gravity, malic acid and tannin content, weight of fruit, yield of juice, and variations in the specific gravity after fermentation and bottling.

The treatment of cider sickness, O. Grove (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1914, pp. 22-24).—Experimental data have demonstrated that cider sickness can be remedied or prevented by either of the following methods: (1) Increasing the acidity, either by mixing a cider of low acidity with one which is naturally high or by adding a sufficient amount of tartaric acid, equivalent to about 0.5 per cent malic acid; or (2) the use of brewer's or compressed yeast. Increasing the acidity has yielded the most desirable results.

The use of sulphur dioxid and aeration yielded negative results.

The relative value of cane and beet sugar for fermentation purposes, O. GROVE (Univ. Bristol, Ann. Rpt. Agr. and Hort. Research Sta., 1914, pp. 32, 38).—In fermentation tests beet sugar was found to yield better results than cane sugar.

"Leaving out of consideration that most of the samples sweetened with cane sugar did not keep, but were attacked by a bacterial disease, whereas all the beet-sugar samples remained in good condition, the flavor of the cane-sugar samples was in all cases inferior. . . That is, the peculiar taste of cane sugar was easily detected, whereas the beet sugar did not give any new flavor to the cider, but simply acted as a neutral sweetener, which, of course, is preferable. This result, being somewhat contrary to previously accepted views, . . . needs further confirmation by fresh experiments before much importance can be attached to it."

The fermentation of cane molasses; composition of rum, Kayser (Ann. Falsif., 9 (1916), No. 90-91, pp. 121-127).—This article indicates the importance of the apparatus and method used in the distillation of rum as affecting its quality, and submits analytical data of a number of samples of rum fermented under varying degrees of acidity, with the use of 3 per cent ammonium fluorid, in the presence of both an abundant and a limited supply of air, and with various yeasts.

On the transformation of the nitrogenous substances during the forced curing of tobacco, L. Bernardini (Ann. R. Seuola Sup. Agr. Portici, 2. ser., 12 (1914), pp. 347-359).—It was found that in the forced curing of tobacco there is no appreciable destruction of protein substances, nicotin, or ammonia. There is, however, a loss of total soluble nitrogen which is apparently due to a loss of amino acids. An oxidation which converts a part of the insoluble nitrogenous substance to a soluble form is also apparent, and may in some degree account for the loss noted.

It is indicated that, while the results submitted do not exclude the fermentation theory of tobacco curing, it appears that the process is nevertheless to a large extent purely chemical.

Note on the detection of faulty sizing in high-grade papers, C. F. Sammer (Jour. Indus. and Engin. Chem., 8 (1916), No. 5, p. 476).

#### METEOROLOGY.

Meteorology in relation to agriculture in Canada, R. W. STUPART and R. W. Mills (Internat. Inst. Agr., [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 2, pp. 177-179).—This article explains briefly what the Meteorological Service of Canada is now doing and plans to do along this line, containing practically the same information noted from another source (E. S. R., 35, p. 15).

Meteorological observations, F. Eredia (Agr. Colon. [Italv], 10 (1916), I, Nos. 1-2, pp. 35-79, pls. 6, figs. 17; 3, pp. 131-150, pls. 4, figs. 13: 4, pp. 190-212, pls. 4, figs. 12; 5, pp. 239-266, pls. 3, figs. 10; 6, pp. 309-322, pl. 1, figs. 6; II, No. 7, pp. 245-280, pls. 2, figs. 10).—This article describes the construction, installation, and operation of meteorological instruments suitable for observations in the Italian colonial possessions.

The frequency of low temperatures at Vercelli (Italy) and its effect on the cultivation of rice, B. MARCARELLI (Gior. Risicolt., 5 (1915), No. 22, pp. 355-360, fig. 1; abs. in Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 2, pp. 192, 193).—It was found that the minimum temperature limits are of great importance in the early stages of the growth of rice, this minimum limit being from 46 to 50° F. The maximum rate of growth was

found to be associated with a high minimum temperature, accompanied by warm, short nights. The highest minimum temperatures occur in Italy in July and the first week in August, when the humidity of the air is relatively high and the days long and very warm. Low temperatures during the last days of July and the first of September occurring at the important and tender stages of heading, inflorescence, and formation of grain caused considerable damage to rice in 1915.

Night frost in the East Indies, W. Van Bemmelen (*Tijdschr. Nijv. Landb. Nederland. Indië*, 92 (1916), No. 2, pp. 126-131).—The conditions under which these frosts occur are briefly discussed.

The weather of Scotland in 1915, A. WATT (Trans. Highland and Agr. Soc. Scot., 5. ser., 28 (1916), pp. 242-256).—The weather conditions for each month are summarized and much detailed data for rainfall at various places in Scotland are given.

It is stated that in the extreme north and in the western and most southern districts there was a well-defined shortage of rainfall, and toward the northwest the shortage was of a most decided character. "In West Inverness-shire the year was the driest on record. At Fort William the rainfall was 30 per cent below the normal, and three-fifths of it was accounted for before the end of April; every month from May onward had a shortage; and May, June, September, October, and November had each less than half the average amount of rain. Outside the northwestern area the extreme southwest appears to have been the region most notable for the persistence of dry periods.

"The severe frost of November seriously interfered with agricultural operations."

[The climate of Pavlovsk], A. V. Shipchinskii (A. Shipchinski) (Zap. Selsk. Khoz. Inst. Imp. Petra I (Mem. Inst. Agron. Emp. Pierre I), 1 (1916), pp. 52-69).—This is a summary of ten years' observations (1897-1904 and 1911-1913). The average annual temperature was 6.9° C. (44.4° F.), the precipitation 500.3 mm. (19.7 in.). The prevailing wind was southeast.

#### SOILS-FERTILIZERS.

Michigan's shifting sands: Their control and better utilization, F. H. Sanford (Michigan Sta. Spec. Bul. 79 (1916), pp. 31, figs. 23).—This bulletin deals with the control and better utilization of about 534,000 acres of dune-formed land bordering on the Great Lakes in Michigan.

"The sand dunes in Michigan are found in four belts on the shores of the three greater lakes. These belts are the Superior Belt, the line of dunes found on the Superior shore of the Upper Peninsula; the South Shore Belt, the belt along the south coast of the Upper Peninsular; the West Shore Belt, that formed by the winds and waters of Lake Michigan upon the west coast of the Lower Peninsula; and the fourth, the East Shore Belt, that washed by the waters of Lake Huron. Geologically the sand dunes are young."

It is concluded that "sand along the Michigan shores can be controlled if proper methods are applied. Certain plants are admirably adapted for use in establishing a 'crust' in which other forms of tree growth must be planted to insure permanent forest cover. By waiting for planted belts to grow into high shelters, certain adjacent belts in the lee may be utilized by the growth of certain forest crops, or orchards, but never by annual crops.

"Studies of planting done from 10 to 20 years ago point out the imperative need of establishing and maintaining a solid cover on the windward slopes of all blows. Planting must begin on the windward side of a blow with the establishment of a facing of low forms that are capable of withstanding the rough treatment to which they will be subjected. In all dune formations where the sand is

cast up by water a control shelter of hardy shrubs must be set as close as possible to the winter line of high water and ice. An artificial barrier of drift material and wood forms a splendid protection and justifies considerable expense up establish it. . . .

"There are two general plans of operation in the work of sand control. The 'shelter belt' or 'barrier' system is suitable to private owners. It may be so managed as to enable the man of limited means to do systematically a portion of the work each year until the whole blow area is under permanent forest cover. The 'entire cover' system calls for heavy expenditure in labor and materials but has as its aim the completion of the work over the whole area in a single season."

Contribution to the knowledge of the weathering of podzol soils of middle Norrland, O. TAMM (Bul. Geol. Inst. Univ. Upsala, 13 (1914-15), I, pp. 183-204, figs. 2; abs. in Chem. Abs., 10 (1916), No. 9, pp. 1243, 1244).—Studies of samples of eight profiles of podzol soils in middle Norrland, Sweden, are reported.

The chemical composition of unweathered soils in the region, with perhaps the exception of clay, appeared to be very uniform. The chemical and mineralogical compositions of soil layers weathered by raw humus acids (bleicherde) were very uniform. The chemical processes involved in raw humus weathering of soils were found to consist of decomposition rather than transformation of the minerals. Apatite and dark colored minerals, such as biotite and hornblende, were the most easily soluble. On the other hand, feldspars were relatively little attacked. A marked formation of kaolin was not observed in cases where the feldspars had been relatively much attacked. An estimate of the amount of change in the original materials brought about by the formation of bleicherde showed that approximately 7.5 per cent of the bases in percentage of original material were dissolved.

A list of 11 references to literature bearing on the subject is appended.

Some problems of the study of forest soils, G. A. R. Borghesani (Internat. Mitt. Bodenk., 5 (1915), No. 3, pp. 225–231, fig. 1).—This is a critical review of the question of forest soils, with particular reference to the useful adaptation of tree kinds to different soils and the function of the covering of forest litter in the maintenance of forest soils. A list of references to literature bearing on the subject is appended.

Chemical and biological notes on cherry orchard soils, A. Harvey and C. H. Hooper (Gard. Chron., 3. ser., 57 (1915), No. 1484, pp. 308, 309; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 8, p. 1067; Chem. Abs., 10 (1916), No 9, p. 1243).—Chemical and mechanical analyses of several samples of orchard soils to determine whether the yield of cherries is a question of chemical and mechanical composition or one of pollination are reported, the results of which are taken to indicate "that very little value can be assigned to figures obtained either in the chemical or mechanical analysis....

"The conclusions to be drawn from observations on the growth and cropping capacity of the cherry trees compared with the analysis of the soils would seem to be that favorable soil influences the actual growth of the tree, but not necessarily its fruiting capacity. The cherry being by nature a free flowering tree, if year by year it does not crop the fault is probably the lack of suitable cross-pollination rather than some fault in the soil."

Investigations on tobacco soils, B. T. P. BARKER (Jour. Bath and West and South Counties Soc., 5. ser., 9 (1914-15), pp. 129-131).—Analyses of a series of samples of American and African tobacco soils are reported.

"The American soils as a group may be described as very coarse-grained sandy soils of feeble water-holding capacity and poor in all the elements of plant food. . . . The African soils, on the other hand, are sandy soils of good

water-holding capacity (on account of the high percentage of organic matter) and well supplied with all the elements of plant food. . . . Compared with the American soils, the African soils (1) are much darker in color, (2) contain much more organic matter (humus) and nitrogen, (3) contain more phosphoric acid and potash, and (4) contain rather more of the finer grades of soil particles. It appears probable that these American and African samples differ essentially in that in the one case the plant food (especially the nitrogen) must be supplied in the form of readily available artificial manures while in the other it can be obtained, in somewhat different form, from the natural reserves of the soil. Therefore, even if the possible effect of differing climates and rainfall is set aside, there are many points of difference between the two groups of soils, any one of which may have an important influence on the quality of the crop."

Red soil, P. V. De Regny (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 9, pp. 1133-1138).—The author reviews work by himself and others bearing on the subject and reports analyses of Karstian red soils from various localities.

It is concluded "that there are similar but not identical types of red soil and that they may have various origins; in nature the same effect is not always produced by the same cause. There are, therefore, red soils of different compositions, more or less ferruginous, or calcareous, or rich in alumina, produced either by direct or by indirect weathering of the limestone or by æolian action.

. . . Red soils, at least in their most typical manifestations, must be considered as of a prevailingly colloidal type of formation."

Analyses of soils of Stewart County, W. A. Worsham, Jr., L. M. Carter, D. D. Long, and M. W. Lowry (Bul. Ga. State Col. Agr., No. 99 (1915), pp. 59, figs. 4).—This bulletin reports general soil survey data of the county, much of which has been previously noted from another source (E. S. R., 34, p. 120), and contains chemical analyses of each soil type mapped, together with a summary of the average of analyses for each type. "Taking the average of all the soils of the county, the analyses show the plant food content to be as follows: Nitrogen 0.025, phosphoric acid 0.045, and potash 0.508 per cent." These results are taken to indicate that nitrogen is the limiting factor of crop production in the county.

Notes on some west country soils, C. T. GIMINGHAM (Jour. Bath and West and South. Counties Soc., 5. ser., 9 (1914–15), pp. 51–61).—The author discusses the physical properties and formation of soils and describes the soils, especially of Gloucestershire, Somerset, and Wiltshire, England, with reference to their relationship to the geological strata underlying them.

A new method for mechanical soil analysis, S. Opén (Internat. Mitt. Bodenk., 5 (1915), No. 4, pp. 257-311, figs. 15; abs. in Ztschr. Angew. Chem., 28 (1915), No. 77, Referatenteil, pp. 486, 487).—A method is described which is based on the rate of sedimentation of the particles of a water suspension of soil as measured by the rate of the increase in weight of the settled matter. Preliminary experiments with the method are also reported. It is thought that this method may be useful in analysis of soils with slight variations in the size of particles of different strata or for saving time in the ordinary analysis. The apparatus used is also described and illustrated.

Judging soils on the basis of the hydrochloric acid extract and process of exchange of bases, A. A. J. von Sigmond (Internat. Mitt. Bodenk., 5 (1925), No. 3, pp. 165-224, figs. 2; abs. in Chem. Abs., 10 (1916), No. 1, p. 80).—It was found that detailed chemical analyses of hydrochloric acid extracts of soils gave characteristic comparative values as to the soil-forming factors which could not be obtained by lump analyses.

It is thought that instructive conclusions may be drawn from the process of base exchange in soils regarding soil-forming factors and also the physical and chemical soil properties.

The cause and nature of soil acidity with special regard to colloids and adsorption, E. Truog (Jour. Phys. Chem., 20 (1916), No. 6, pp. 457-484; abs. in Chem. Abs., 10 (1916), No. 18. p. 2381).—This is a review of a large amount of literature bearing on the subject and a general summary of the results of the laboratory research work on the subject at the Wisconsin Experiment Station.

It is maintained that the existence of selective adsorption of ions from the common alkali and alkaline earth salts is questionable. "The phenomenon observed in acid soils and often designated as selective adsorption of ions is of an entirely higher order in extent, and comparable in every way to chemical reactions between acids, bases, etc. . . . It is shown that, when the conditions are properly controlled, it can be demonstrated that the reactions due to soil acidity take place according to chemical equivalence and exhibit all the properties of true chemical reactions.

"The possibilities for the formation of true acid substances in soils of the humid region are manifold and it would be extremely difficult to explain why such substances should not be formed. In most upland soils mineral acids, i. e., kaolinite and other acid silicates, are the main cause of soil acidity. Soils high in organic matter may contain considerable amounts of organic acids. These acid substances may be either in the crystalloidal or colloidal condition and their acid reaction is due to their chemical nature and not colloidal condition."

Preliminary studies on heated soils, J. Johnson (Science, n. ser., 43 (1916), No. 1108, pp. 434, 435).—The results of experiments conducted at the University of Wisconsin are reported. It was attempted mainly to correlate the chemical changes produced in heated soils with their effect upon seed germination and plant growth. The conclusions drawn are considered to apply particularly to soils heated above 100° C. Various seeds were used, especial use being made of cabbage.

"The results in general were similar for the different seeds, though they varied much in their susceptibility to the injurious action. Lettuce and clover seeds were very susceptible to the injurious action of highly heated soils, whereas rye and buckwheat were very resistant. Plant growth is affected in much the same manner, wheat, for example, recovering rapidly from the deleterious action of certain heated soils where tomatoes appeared to be permanently injured.

"Different soils give markedly different results upon heating to the same temperatures. The action appears to be dependent particularly upon the content of organic matter in the heated soil. . . .

"The temperature to which the soil is heated is seemingly the most important factor in determining the extent of the injurious or beneficial action. Approximately 250° was found to be the most critical temperature in all the soils used. At this temperature seed germination was most strikingly retarded. Early plant growth was usually checked for the longest period of time on soils heated to 250°, although late plant growth, in the case of some crops at least, was most vigorous on these soils. Heating to temperatures of 300°, or above, in all the soils used again reduced the injurious action to seed germination and early plant growth, as well as the beneficial action to late plant growth. Heating soils to 250° produced greater amounts of material extractable with water than heating to higher or lower temperatures. The ammonia content of the soil increased proportionally to the temperature of heating up

to about 250°, after which it rapidly fell to a minimum. The increase in ammonia was accompanied by a decrease in nitrates, which were practically non-existent in the highly heated soils. . . .

"The percentage of seed germination has been found to be closely correlated with the amount of ammonia present in the heated soils studied. The amount of ammonia required to injure germination, however, appears to vary with the type of soil when comparisons of different heated soils are made. It appears that the absorptive power of the soil is a very important limiting factor in determining the extent of the injurious action.

"The presence of dihydroxystearic acid... could not be demonstrated in the most toxic of the heated soils. That the toxic substance is of a volatile nature is evidenced by the fact that it is readily removed from the soil by aeration... The evidence at hand points toward the formation and injurious action of ammonium carbonstes particularly. These salts being unstable in the soil, except when kept in a dry and unaerated condition, accounts for the gradual disappearance of the injurious action of heated soils. It also appears that other compounds of ammonia are formed which are more stable in character. The beneficial action of heated soils on plant growth, especially of those heated between 150 and 250°, is believed to be due in a large part to the direct assimilation of ammonia or ammonium compounds by the plants."

Changes in soils brought about by heating, Miss A. Wilson (Notes Bot. School Trinity Col. Dublin, 2 (1916), No. 6, pp. 311-318, figs. 3).—The substance of this article has been noted from another source (E. S. R., 34, p. 722).

The occurrence of bacteria in frozen soil, E. C. Harder (Bot. Gaz., 61 (1916), No. 6, pp. 507-517, figs. 2).—Experiments conducted at the University of Wisconsin with field and potted soil to determine the effect of cold and moisture on bacterial numbers are reported.

It was found that "the number of bacteria in surface soil increased markedly after heavy frosts and in general maintained a high average during the winter months. The increases and decreases, however, were found to bear a distinct relation to the moisture content. The potted soils failed to show such marked increase in bacterial content after frosts. On the contrary, the enriched cultures showed a distinct retardation of bacterial growth when in a frozen condition. The bacterial flora was more or less the same during the fall, winter, and spring, with the exception that after heavy frosts the small transparent colonies characteristic of water and of deeper soils formed a larger proportion of the growth on the plates.

"From these results it seems reasonable to conclude that ordinary soil bacteria undoubtedly withstand cold to a marked degree, even to temperatures as low as 4° C. or more below zero. The increase in numbers, however, seems to be due to mechanical transportation by moisture coming up from below during heavy frost, and where such transportation is not possible there is an actual retardation in growth as compared with that in unfrozen soils."

Soil bacteria and phosphates, C. G. Hopkins and A. L. Whiting (*Illinois Sta. Bul. 190 (1916*), pp. 393-406).—A general review of present knowledge of the subject is given, together with the results of experiments on the solution of rock phosphate by nitrite and nitrate forming bacteria.

It was found that "nitrite bacteria make phosphorus and calcium soluble from insoluble phosphates when they oxidize ammonia into nitrite. The actual ratio found shows that about 1 lb. of phosphorus and about 2 lbs. of calcium are made soluble for each pound of nitrogen oxidized, aside from the action of the acid radicles associated with the ammonia. . . . Neither ammonia-producing

bacteria nor nitrate bacteria liberate appreciable amounts of soluble phosphorus from insoluble phosphates."

It is pointed out that "plants are important factors in the liberation of phosphorus, owing to the production of carbon dioxid and the removal of the soluble phosphorus produced by the bacteria... Other acid-producing bacteria make phosphorus soluble from insoluble phosphates according to the nature and amount of the acid produced. A comparison of the amounts of nitrogen, phosphorus, and calcium required by farm crops, with those possible of solution by biochemical action, shows possibilities far beyond the plant requirements, which leads to the conclusion that plenty of rock phosphate in contact with decaying organic matter must give the plants an excellent opportunity to obtain both phosphorus and calcium as well as nitrogen."

Disinfection experiments on moor soil, A. von Nostitz (Landw. Jahrb., 48 (1915), No. 4, pp. 587-606, pl. 1, figs. 3; abs. in Ztschr. Angew. Chem., 29 (1916), No. 16, Referatenteil, p. 98; Chem. Zentbl., 1916, I, No. 3, p. 115).—Experiments with upland moor soils on the influence of carbolineum, calcium chlorid, and potassium permanganate when used as soil disinfectants are reported. Carbolineum was found to give better results than calcium chlorid.

The use of the disinfectants was accompanied by marked increases in crop yield, especially in the case of carbolineum. Carbolineum gave better results the earlier it was used before seeding and gave the best results when used at the rate of from 50 to 60 gm. per square meter of soil. Carbolineum rich in volatile constituents was more effective than when poor in these constituents. The action of carbolineum was especially marked with reference to its influence on the bacteria and nematode contents of soil.

Niter spots, W. Stalder (Science, n. ser., 43 (1916), No. 1116, pp. 712, 713).— The author refers to the theories of Sackett and of Stewart and Peterson regarding the origin of brown niter spots in arid soils (E. S. R., 25, p. 815; 33, p. 121), and reports his observations on niter spots in northwestern Nevada, which showed that the feces of jack rabbits when coming in contact with alkali water or moist alkali soil decomposed comparatively rapidly, forming brown spots containing nitrates. It is concluded "that the brown niter spots of the playas were, as far as examined, of animal origin. From these observations it is safe to predict that in fields of the arid western States brown niter spots will appear when live stock is pastured in the same and alkaline waters are used for irrigation."

Acid phosphate versus raw rock phosphate as fertilizer, A. T. Wiancko and S. D. Conner (Indiana Sta. Bul. 187 (1916), pp. 1055-1082 fig. 1).—This bulletin reports the results of 82 comparative tests of acid phosphate and raw rock phosphate which have been made by the Indiana Station since 1904. Series of tests covering varying lengths of time, but an average of 3.47 years, are reported, which "are believed to give a fair comparison of the use of the two phosphates under average Indiana field conditions with various crops and during different seasons on a large number of soil types." The crops grown included rotations of corn, wheat, and clover or soy beans, and potatoes and soy beans. The applications of acid phosphate varied from 150 to 500 lbs. per acre, averaging 205 lbs. and were valued at \$16 per ton; of the rock phosphate from 350 lbs. to 1 ton, averaging 545 lbs. and valued at \$7.50 per ton. The phosphates were used alone and combined with manure and were supplemented by applications of limestone when liming of the soil was deemed necessary.

The results are summarized in the following table:

Summary of 82 comparative tests of acid phosphate and rock phosphate on different crops and soils.

Crop.	Num- ber of tests.	Kind of phosphate.	Averages per acre per year.					
			Yield.	In- crease.	Value of increase.	Phosphate used.	Cost of phosphate.	Profit or loss.
Corn	36	Acid phosphate	Bushels. 43.04 42.20 37.55	Bushels, 5.49 4.65	\$2.95 2.52	Pounds. 190. 5 532. 0	\$1.52 1.86	\$1.43 .66
Wheat	33	Acid phosphate Raw rock None	15. 28 12. 88 10. 97	4.31 1.91	4.63 2.12	190. 5 532. 0	1.52 1.86	3.11
Legume hay	9	Acid phosphateRaw rock.	Pounds. 2,998 2,773 2,678	Pounds. 320 95	1.60	190. 5 532. 0	1.52 1.86	. 08 -1. 39
Potatoes	4	Acid phosphate	112.0	Bushels. 29.4 11.6	14.70 5.80	500 1,000	4.00 3.50	10.70 2.30
Average	82	Acid phosphate			4.06 2.29	205 545	1.64 1.91	2. 42 . 38

¹ Value of increase includes value of corn stover and wheat straw.

It is estimated from the average results that the profit per dollar invested was over seven times as great from acid phosphate as from rock phosphate. The value of the crop increase per pound of phosphorus applied was 28½ cts. for acid phosphate and 3.5 cts. for rock phosphate.

Red soils and phosphatic manuring, J. Arie (Bol. Agr. [São Paulo], 15. ser., No. 6-7 (1914), pp. 535-555, figs. 2; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 8, pp. 1042-1044).—This report deals with the problem of manuring red soils, especially those of the State of São Paulo, Brazil, derived from the decomposition of diabasic rocks.

A series of analyses of these soils showed "that out of 48 samples, 4 contained only traces of phosphoric acid, 12 up to 0.5 [parts] per thousand, 15 from 0.5 up to 1 per thousand, 10 from 1 up to 1.5 per thousand, 6 others up to 3.6, and 1 even 5.2 per thousand. Humus is relatively low, from a minimum of 0.24 per cent up to 2.56 per cent exceptionally, but generally about 1 per cent. The lime content varies from 0.01 to 0.65 per cent. From these data and from other analyses . . . it appears that 60 per cent of the soils examined were in urgent need of phosphatic manuring. . . .

"Experiments were also made in order to determine the absorptive capacity of red soils for phosphoric acid, solutions of monocalcium phosphate being placed in contact with the soil samples." It was found that the phosphoric acid was almost entirely absorbed after 20 days of contact, but this absorption was accompanied by an insolubility and consequent retrogression of the phosphate.

"The most important factors in this fixing of phosphoric acid are lime and humus. When a more calcareous red soil was taken 0.22572 gm. was absorbed at the end of 20 days instead of 0.214608 gm. Humus contributes to regulate the absorption, but . . . it serves still more to retard and prevent the retrogression. Consequently the best way of decreasing the effects of retrogression in red soils is to turn in organic plant manures, and especially dung, as often and as regularly as possible. . . .

"When . . . superphosphate is employed the author recommends that dung should always be used according to the following rules: (1) The dung should be well decomposed . . ., and (2) it should be well mixed with the superphosphate shortly before application, according to the phosphate content of the soil and the requirements of the crop, at from 1 to 2 cwt. of superphosphate per ton of well-decomposed dung."

Electro-potash as a fertilizer, S. Rhodin (K. Landtbr. Akad. Handl. och Tidskr., 54 (1915), No. 8, pp. 710-729; Meddel, Centralanst. Försöksv. Jordbruksområdet, No. 119 (1915), pp. 22; abs. in Chem. Abs., 10 (1916). No. 7, p. 948).— This is a progress report of field experiments with electrically-treated feldspar. The products of the Lindblad and Yngstrom method are so far the most promising. The fertilizing value of these substances was found to be very largely dependent upon the nature of the humus in the soil, type of plant, and vegetation period.

Influence of calcium and magnesium compounds on plant growth, F. A. WYATT (U. S. Dept. Agr. Jour. Agr. Research, 6 (1916), No. 16, pp. 589-620, pls. 6).—Experiments conducted at the Illinois Experiment Station on the effects of calcium and magnesium on wheat, alfalfa, soy beans, cowpeas, oats, timothy, and sweet clover when applied in different natural and in artificially prepared forms, and to determine the amount of calcium and magnesium which the plants could tolerate, together with the relation between the ratios of these two elements in the plants, in the soils, and in the materials applied, are reported.

"Dolomite, limestone, magnesite, calcareous soils, and brown silt loam were used as souces of the natural forms, while prepared materials, such as the carbonates, chlorids, and sulphates served as sources of the artificial forms. . . . The earlier applications varied from 0.1 to 0.6 per cent of magnesium added in magnesium carbonate and in magnesite. Later the following amounts were employed: 2, 6, and 10 per cent of magnesium in magnesite; 10 and 12.7 per cent of magnesium in dolomite; 0.1, 0.01, and 0.001 per cent of magnesium in the carbonates, chlorids, and sulphates. In each series sand or soil was used as a control."

The following conclusions are drawn:

"Wheat, soy beans, alfalfa, and cowpeas grew normally either in 96 per cent of dolomite and 4 per cent sand, 100 per cent of magnesian limestone, or in sand containing 8 per cent of magnesite. Dolomite up to 40 per cent proved beneficial to plant growth. These results indicate that dolomite and magnesian limestone will not be detrimental as applied in agricultural practices. Applications of prepared magnesium carbonate up to 0.7 per cent caused no injury in brown silt loam, but 0.35 per cent prevented the growth of all plants tested in sand.

"The crop yields and the ratio of calcium to magnesium in the plants bear no direct relation to the ratio in the natural carbonates applied. Different ratios of calcium to magnesium within rather wide limits produced no marked differences in yields. Increasing the size of applications increased the calcium and magnesium content of plants.

"A tolerance of calcium and magnesium occurred in all varieties of plants grown. With approximately identical yields, wheat straw grown in sand, brown silt loam, dolomite, and soil containing 35 per cent of magnesite showed calcium contents varying between 0.165 and 0.547 per cent and magnesium contents varying between 0.132 and 0.955 per cent.

"Acid extractions failed to remove all the calcium and magnesium from the sand. There remained after the various extractions from 768 to 852 mg, of calcium and from 540 to 960 mg, of magnesium per 6,000 gm. of sand. The

plants possessed a decided ability to obtain calcium and magnesium from sand extracted with strong hydrochloric acid."

A list of 42 references to literature bearing on the subject is appended.

Sour soils and liming, W. Frear (Penn. Dept. Agr. Bul. 261 (1915), pp. 221).—This bulletin, a revision of Bulletin 61 (E. S. R., 12, p. 327). deals with soil acidity and the use of various limestone products for its correction, the object being to present in logical order the present knowledge on the subject, with special reference to the results of American studies, particularly those made at the Pennsylvania Experiment Station. An extensive set of practical conclusions is included, most of which have been noted from other sources, especially the Pennsylvania Station reports.

It is concluded that in soil formation the rocks lose much of their basic materials, lime especially, the final result of which is an acid residue, particularly where colloidal minerals and organic residues from decay accumulate. "This acid condition is immediately due to a great variety of materials, some the result of soil weathering, some of crop action, in slight degree of the early products of plant decay; often, and in much greater degree, of the later, more resistant residues from decay; and finally to various additions, fertilizers, or substances added for other purposes. When the acidity-producing substances are themselves readily decomposable plant materials, their early destruction usually follows, and their alkaline mineral constituents are released. As a result, their acid effect is only temporary. When, however, the cause is an unsatisfied colloid, mineral or organic, a material but slowly decomposable in the soil, the acid condition is permanent, though variable in degree, as conditions of cropping, cultivation, etc., tend to increase or decrease the acidity. . . .

"Soil cultivation hastens the decay of organic materials... The tendency of stirring the soil, as by the use of cultivated fallow, should be to reduce acidity... The acid-producing effect of commercial fertilizers is usually not very great. The nitrates tend to leave alkaline residues. The acid phosphates take very little lime to make them neutral or alkaline. Calcium sulphate is, in silty loam soil, of but slight effect, although on clay loams and clays it may be more active. The potash salts, in the amounts ordinarily applied, are not of large influence in this respect. Thomas slag is mildly alkaline in its effect. Ammonium sulphate is the most conspicuous producer of acidity. Its continuous use inevitably tends to produce pronounced acidity in the soil...

"The kinds of plants occurring on a soil and the manner of their growth usually give the first evidence of [acidity]. Clover failure . . . and the replacing of the sweet grasses by plantain, moss, and sorrel, are the common signs. . . . Careful cultivation stimulates soil fermentations. These will, sooner or later, destroy temporary acidity. Mild acidity of a more permanent character may be overcome by the use of nitrate of soda and basic slag, both of which have alkaline residual effects. Where, however, the acidity is pronounced . . . lime, pulverized limestone and leached wood ashes, marls, and oyster shells, burned or raw and pulverized, are the only materials powerful enough and cheap enough for the purpose."

Lime and its uses in agriculture, R. HARCOURT (Ontario Dept. Agr. Bul. 238 (1916), pp. 12).—This bulletin deals with soil acidity, the forms and uses of lime in agriculture, and the action of lime in soils.

Liming and inoculating soils, C. S. DORCHESTER, T. R. DOUGLASS, and P. C. TAFF (Iowa State Col. Agr. Ext. Bul. 40 (1916), pp. [4], figs. 3).—The general lime requirements of Iowa soils are discussed. Ground limestone is considered the best kind of lime to use on these soils. Methods of inoculation of soils for legume growing are also briefly described.

The relation of sulphur to soil productivity, F. L. DULEY (Jour. Amer. Soc. Agron., 8 (1916), No. 3, pp. 154-160).—Sand and silt loam soil culture experiments conducted at the Missouri Experiment Station to determine the influence of flowers of sulphur and other sulphur compounds on corn, rape, and clover and on soil with no crop are reported. Analyses of samples of nine of the more important soil types of the State showed sulphur contents varying from 0.014 to 0.053 per cent.

It was found that "flowers of sulphur partly took the place of a soluble sulphate in a nutrient solution when used in a sand medium and had a marked effect upon the production of chlorophyll in corn plants. When used alone flowers of sulphur was slightly beneficial to the growth of corn and rape, and still more beneficial to the yield of red clover on the type of soil used in these experiments. Flowers of sulphur very markedly increased the production of nodules on the roots of red clover [and] was oxidized to sulphate in both sand and soil cultures. It slightly increased soil acidity and the lime requirement was directly correlated with the amount of soluble sulphate. The nitrate content varied inversely with the amount of soluble sulphate in the soil."

Can lithia be a constituent of plant food? P. D. Hahn (So. African Jour. Sci., 12 (1916), No. 6, pp. 227-229).—Experiments are reported which indicate "that lithium compounds in the presence of potassium compounds do not influence the growth of wheat in water cultures during the first period of vegetation, whereas in the later period the growth of the plants is rather retarded and the formation of grains prevented."

[Analyses of fertilizers and fertilizing material], R. E. ROSE and F. T. WILSON (Fla. Quart. Bul. Agr. Dept., 26 (1916), No. 2, pp. 98-115).—This section contains the results of actual and guarantied analyses of 167 samples of fertilizers and fertilizing materials offered for sale in Florida in 1916.

Commercial fertilizers, W. J. Jones, Jr., F. D. Fuller, E. G. Proulx, R. B. Deemer, R. B. Bitler, and H. C. Mugg (*Indiana Sta. Bul. 186 (1916*), pp. 1052).—This bulletin contains the results of actual and guarantied analyses of 1,368 samples of fertilizers and fertilizing materials offered for sale in Indiana during 1915.

Official report [of Ohio] on commercial fertilizers and agricultural lime licensed, inspected, and analyzed during the year 1913 (Ann. Rpt. Ohio Bd. Agr., 68 (1913), pp. 401-633).—This report contains a number of brief popular special articles on fertilizers and their uses, and the results of actual and guarantied analyses of 814 samples of fertilizers and fertilizing materials and of agricultural lime collected for inspection in Ohio during 1913, together with a list of licensed brands of fertilizers.

#### AGRICULTURAL BOTANY.

Life cycles of the bacteria, F. Löhnis and N. R. Smith (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916) No. 18, pp. 675-702, pls. 7, fig. 1).—According to the authors, under certain conditions all bacteria pass over into an amorphous or "symplastic" stage, appearing under the microscope either as an unstainable or a readily stainable mass without any easily distinguishable organization, which, if not discarded as dead, later gives rise to new regenerated forms frequently of characteristic and unusual appearance. In a study of 42 strains of bacteria, it was found that all lived alternately in an organized and in an amorphous stage. It is also stated that bacteria multiply not only by fission but by the formation of gonidia, some of which are filterable and produce new bacteria either directly or after having entered the symplastic stage. The

life cycle of each species of bacteria studied was found to embrace several subcycles showing wide morphological and physiological differences.

Studies of Bacillus radicicola, J. C. Temple (Georgia Sta. Bul. 120 (1916), pp. 67-80, figs. 6).—Studies are reported of the use of cultures for inoculating legumes and of the employment of sterilized soil as a medium for growing B. radicicola.

A number of commercial cultures were tested on different media, including soil, and the number of viable bacteria in the sample was determined. The results given in detail in a table show a relatively high bacterial content of the cultures grown in soil. To secure data on the life of *B. radicicola* on dry seed Canada field peas were inoculated and stored in a loosely stoppered bottle after drying. Seeds from this lot were planted in bottles of sterilized sand at intervals of thirty days. Nodules were formed on all plantings up to the fifth month.

The purpose of the study of sterilized soil as a medium for growing *B. radicicola* was to determine whether this organism grows more vigorously in soil than in the usual culture solutions, and how the longevity of the two kinds of cultures compares.

Two sets of samples were started May 22, 1912, one inoculated with *B. radicicola* from soy bean and the other with the similar organism from crimson clover. Counts of the soy bean culture made on different dates showed that from the second week on the number of bacteria in the soil greatly exceeded the number in solution and in the soil the increase continued as long as the tenth week, while in the solution the maximum was reached in two weeks when the number of bacteria was only about one-tenth that in the soil sample. The crimson clover culture grew less vigorously but the soil appeared to be much more favorable for its development than the culture solution. The soil culture used March 17, 1916, to inoculate crimson clover in tubes was able to produce numerous nodules. Similar results were secured with alfalfa cultures. In each experiment the soil cultures showed the greater longevity.

An experiment was conducted also to determine what influence various substances used in the preparation of media have on the development of *B. radicicola* in solutions and in soil. The results indicated that of the different sugars used cane sugar and dextrose were very much superior to lactose, while levulose was of no value. A repetition of the experiment also indicated that levulose was entirely unsuited to this organism. The presence of ground alfalfa caused rapid multiplication in solution and in soil, the larger number being in the soil.

The evidence brought out by these experiments indicated that of the different media compared sterilized soil, with the addition of a small amount of leguminous material, was the best medium for the propagation of *B. radicicola*.

The influence of energy material upon the relation of soil micro-organisms to soluble plant food, C. J. T. Doryland (North Dakota Sta. Rul. 116 (1916), pp. 319-401, figs. 2).—Following a review and discussion of previous work, results are given of an extended study of six common ammonifying organisms to test their ability to consume ammonia in the presence of dextrose as a source of energy. The organisms used were Bacterium mycoides, B. subtilis, B. megatherium, B. proteus, B. vulgatus, and Sarcina lutea. In the experiments the author investigated the ability of these organisms to grow and produce ammonia from casein in both the presence and the absence of dextrose; the effect of increasing quantities of dextrose upon the number of bacteria and the ammonia production in the casein solution; the competitive action between the ammonifying bacteria and maize seedlings when grown in the presence of dextrose; the effect of adding ammonium sulphate, potassium nitrate, casein, or manure on the growth of oats in quartz sand to which dextrose had been added; the

ammonia and nitrate consuming power of certain soils; and the effect of dextrose and straw upon this consuming power.

All the organisms were found capable of assimilating ammonia from ammonium sulphate when dextrose was present as a source of energy. The presence of dextrose was not found to inhibit the multiplication of organisms in casein solution, but it did sometimes lessen the amount of casein decomposed. All the bacteria experimented with in synthetic solutions containing dextrose and all pecessary plant food elements with ammonium sulphate as a source of nitrogen successfully competed with maize seedlings for plant food elements when grown in quartz sand containing 12 per cent moisture and maintained under conditions that exclude other organisms. Under the conditions of the experiment the difference observed in the growth of maize seedlings in the presence and the absence of dextrose is attributed almost wholly to the competitive action of the bacteria. The author claims that soils have a definite nitrogen and ammonia consuming power and that when large quantities of straw are added to the soil there is a marked decrease in the ammonifying power and a marked increase in the ammonia and nitrate consuming power. Within certain limits the number of bacteria and the ammonification of casein by B. mycoides is proportional to the quantity of phosphorus or potassium added, when these elements are present in limited amounts.

As a result of his investigations the author is led to believe that the so-called ammonia-consuming power can not be used as an index of soil fertility. Molds are considered to play an important part in the aerobic decomposition processes of the soil, and they have been found active in the assimilation of plant food constituents during the first stages of decomposition of crop residues and later may play as important a part as bacteria in liberating plant food constituents. Yeast and algae are also considered possible important factors in this regard.

The scope and relations of taxonomic botany, A. S. Herchcock (Science, n. ser., 43 (1916), No. 1106, pp. 331-342).—This is the address of the retiring president of the Botanical Society of America delivered at Columbus, Ohio, on December 29, 1915.

Drug plants of North Dakota, MAE A. ENGLEHORN (North Dakota Sta. Spec. Bul., 4 (1916), No. 6, pp. 132-148).—Descriptive lists are given of some drug plants native to North Dakota, 21 of the species being recognized as official, 9 formerly so considered, and 39 unofficial drug plants which are thought to have some therapeutic value.

Notes on Quamasia with a description of a new species, C. V. PIPER (*Proc. Biol. Soc. Wash.*, 29 (1916), pp. 77-81).—Notes are given on a number of species of the genus Quamasia, and Q. walpolei n. sp. is described.

Branching and flowering habits of cacao and patashte, O. F. Cook (U. S. Nat. Mus., Contrib. Nat. Herbarium, 17 (1916), pt. 8, pp. IX+609-625, pls. 11).—Results are given of field studies of the characters and habits of the cacao tree (Theobroma cacao), together with the related food tree, Tribroma bicolor.

The double stock, its history and behavior, Edith R. Saunders (Jour. Roy. Hort. Soc., 40 (1915), No. 3, pp. 450-472).—This is a lecture delivered at the meeting of the British Association for the Advancement of Science in Australia in August, 1914.

In giving more particular attention to the fact that the proportion of doubles in a college garden at Cambridge was found to be far in excess of expectations, the author states that this appears from experiments to result ordinarily from a process of unconscious selection by the gardener in favor of the plants producing doubles by taking more forward and better grown plants to fill the beds and discarding the rest. The strain is always kept going, the seed har-

vested in one year supplying the plants for the next season but one. Single plants were found to be slower growing from the first and to present a less robust appearance at the time of planting out than their sister doubles of the same sowing. The results of the tests made entirely refute the statement that this particular strain is in any way exceptional as regards the output of doubles. It is thought that when the vegetative period is sufficiently prolonged to render the method of selection by vigor practicable, this method may be successfully employed by the gardener, securing in this way a much larger proportion of doubles than is ordinarily obtained.

A suggested explanation of the abnormally high records of doubles quoted by growers of stocks (Matthiola), Edith R. Saunders (Jour. Genetics, 5 (1915), No. 2, pp. 137-143).—The author states that she is now able to give in full the evidence upon which rests the main conclusion in her paper noted above. This evidence is said to be based upon a comparison of results obtained in the flower bed with those of a controlled experiment employing the same materials, showing that the apparent excess output of doubles in the first case is fictitious, and upon a comparison of the number of singles and doubles recorded among the more and the less vigorous individuals, respectively, showing that a proportion in excess of expectation furnished by the more vigorous individuals is counterbalanced by a corresponding deficit among the less vigorous plants. The conclusion is reached that doubles on the whole develop more rapidly and vigorously than singles, and that when the period of development is sufficiently prolonged, selection based upon this difference can be used as a means of securing a higher number of doubles in the beds than corresponds with the actual number from the parent plants.

On the relation of half-hoariness in Matthiola to glabrousness and full hoariness, Edith R. Saunders (Jour. Genetics, 5 (1916), No. 3, pp. 145-158).—An account is given of further studies of the relation between hoariness or glabrousness and sap color. These studies are said to establish fully the conclusions formulated in a previous report (E. S. R., 28, p. 228).

The results recorded in this and the earlier paper are considered to form a concordant body of facts concerning surface character which the suggested scheme of factor relations allows to be brought together in a comprehensible whole. These factor relations are supposed to involve five factors, which interact as three distinct pairs. The behavior of the different paired factors is described at length.

Pollen sterility in relation to crossing, R. R. Gates and T. H. Goodspeed (Science, n. ser., 43 (1916), No. 1120, pp. 859-861).—Preliminary observations made on a number of species of plants indicate that geographically isolated species do not invariably have good pollen and that pollen sterility is by no means a sure sign of hybridity. Pollen sterility is considered a physiological condition which occurs in all degrees of intensity and may be due to a variety of causes, hybridity being one of them.

On the germination of the pollen grains of apple and other fruit trees, J. Adams (Bot. Gaz., 61 (1916), No. 2, pp. 131-147).—Giving the results of preliminary observations made in 1913 regarding the germination of pollen grains in cane sugar solutions ranging in strength from 2.5 to 50 per cent, most of the experiments relating to apple, the author states that some varieties of the same species appeared to have more vigorous pollen grains than others. The pollen grains germinated either in light or in darkness. The quickest germination was observed at temperatures of 21 to 23° C. (69.8 to 73.4° F.). A few pollen grains of apple formed short tubes after being kept dry for three months, some of pear after ten weeks. Pollen grains of strawberry, loganberry, and raspberry were dead after two months, those of black currants after eleven weeks.

Vegetative succession under irrigation, J. F. Macbride (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 19, pp. 741-760, pls. 8).—In a contribution from the Wyoming Experiment Station, the author gives an account of observations on vegetative succession under irrigation on a ranch in Albany County, Wyo.

In order to increase the yield of hay from this ranch, irrigation was resorted to, and it was found that the artificial formation of natural meadows is brought about by a gradual change divisible into several stages each of which is characterized by one or more particular species of plants. The relative permanence of these stages may be controlled by regulation of the water supply. Agropyron spp. and Deschampsia caspitosa are said to furnish the most valuable hay.

A single climatic index to represent both moisture and temperature conditions as related to plants, B. E. Livingston (Abs. in Science, n. ser., 43 (1916), No. 1106, p. 362).—A method is described by which the indexes of precipitation, atmospheric evaporating power, and temperature efficiency for plant growth for any period of time may be combined into a single index of moisture-temperature efficiency. Based on this index, a new climatic chart of the United States for the period of the average frostless season has been prepared.

A living climatological instrument, B. E. LIVINGSTON and F. T. MCLEAN (Abs. in Science, n. ser., 43 (1916), No. 1106, pp. 362, 363).—The authors describe a method for comparing the effectiveness of climates in promoting the growth of standard plants.

In these experiments soy beans were grown in pots always filled with the same kind of soil, the seed being soaked in water at a given temperature for a certain time before planting. Measurements were made on the plant after two and again after four weeks, when the cultures were discontinued. New cultures were started every two weeks and the climatic efficiency for plant growth was determined from the plant measurements made after two and four weeks. The value of the climate for any two to four week period at any station may be compared with that for any other period at the same or at any other station.

The daily march of transpiring power as indicated by the porometer and by standardized hygrometric paper, S. F. TRELEASE and B. F. LIVINGSTON (Abs. in Science, n. ser., 43 (1916), No. 1106, p. 363).—The authors have determined the transpiring power of the lower surfaces of Zebrina leaves by means of standardized cobalt chlorid paper, and at the same time porometer readings were made.

It was found that the porometer rates furnish data for deriving stomatal diffusive capacity, but that this capacity is not quite proportional to transpiring power. Transpiring power was found mainly dependent upon the degree of stomatal opening, but other conditions were influential.

The transpiring power of plants as influenced by differences of altitude and habitat, F. Shreve (Abs. in Science, n. ser., 43 (1916), No. 1106, p. 363).—Measurements were made of the transpiring power of the leaves of some 20 species of plants in the desert and encinal regions of the Santa Catalina Mountains in southern Arizona in the arid foresummer of 1915. The species investigated belonged to different life forms, which were found to differ in their transpiring power and in the character of its daily changes. The same species exhibited a higher transpiring power in the individuals which grow in the flood plains than in those which grow on arid slopes. The daily changes in the former individuals are concordant with the daily march of evaporation, while in the case of the latter the transpiring power falls sharply before the daily maximum of evaporation is reached. A comparison of the transpiring power of the same species at different elevations has shown that the daily check is applied earlier

in the day at lower elevations and later at higher ones. The values for the transpiring power in all cases were found to be higher at the lower elevations, but at the higher elevations the values are sustained through a longer portion of the day.

The interrelation of transpiration, root absorption and water-absorbing capacity of tissues in an Opuntia, Edith B. Shreve (Abs. in Science, n. ser., 43 (1916), No. 1106, pp. 361, 362).—The author gives a summary of investigations conducted to test the conclusion of other workers that the transpiring power is greater in cacti during the night than during the day.

As a result of her investigation it was found that the transpiring power is greatly influenced by light intensity, air temperature, water content of tissues, and available soil water. The day to night variations in transpiring power of tissue are independent of any day to night variations in root absorption. During the daylight hours more water was absorbed by the root than was lost by transpiration, while at night the reverse was true. Variations in water intake by the roots are due, on the one hand, to variations in the soil retentivity, and, on the other, to variations in the plant itself. Stomata, as a rule, are shut during the day and open at night, but it was not possible to ascertain whether the closing of the stomata accompanies or follows a decrease in transpiration rate. The water-absorbing power of pieces cut from internal tissue was less during the night than during the day, being least from 4 to 5 a.m. and greatest from 3 to 5 p. m. This was true whether the calculations were based on dry weight or on the original weight of the material. The author advances the theory that the water-absorbing capacity of the internal tissue controls the secondary absorbing power of the roots, and probably also the transpiring power.

The influence exerted by light intensity and air temperature, together with their duration, show that the variations in absorbing capacity are due, at least in part, to chemical changes brought about by the metabolic processes, and many tests show that the changes in the water-absorbing capacity of the tissues parallel acidity changes in the plants in such a way that when acidity is highest the absorbing capacity is lowest, and vice versa. Certain exceptions occur, however, which show that the relation can not be so simple as the influence of mere changes in hydrogen ion concentration. Other factors, it is claimed, must be taken into consideration, including the accumulation and disappearance of the salts of organic acids. The author claims that it is impossible to state as yet whether the absorbing capacity of the internal tissue is due to colloidal absorption, osmotic forces, or both.

Measurement of the surface forces in soils, C. A. Shull (Abs. in Science, n. ser., 48 (1916), No. 1106, p. 361).—An examination of the absorption of water by dry Xanthium seeds is said to have shown that the internal forces had an initial value of at least 965 atmospheres. The internal forces have been determined at various moisture contents. Dry seeds were used to measure the surface holding power of soils for water, with the result that both the seeds and air dry soil were found to have approximately the same force.

As the capillary moisture increased, the surface moisture decreased until, at the wilting coefficient of the soil, the amount of back pull exerted was not more than 3 or 4 atmospheres. This relation was found to hold essentially for all types of soils from heavy clay to sand. The soil, at the critical moisture content of the plant, it is claimed, holds the water with less force than the osmotic pressure of the root hairs of the plant, as determined by plasmolytic methods. The wilting of the plant, it is believed, does not result from lack of moisture or lack of a gradient toward the plant, but probably from the low rate of movement of water due to the friction in thin films.

Fiber measurement studies: A comparison of tracheid dimensions in long-leaf pine and Douglas fir, with data on the strength and length, mean diameter and thickness of wall of the tracheids, Eloise Gerry (Abs. in Science, n. ser., \( \beta \) (1916), No. 1106, p. 360).—This is a progress report on fiber dimension studies as a part of the investigation into the mechanical, physical, and chemical properties of the longleaf pine (Pinus palustris) and Douglas fir (Pseudotsuga taxifolia), the work being conducted at the Forest Products Laboratory, United States Department of Agriculture, Madison, Wis. Data were collected from microscopic investigations made at every tenth annual ring on large cross sections from old trees.

The results obtained show no evidence of a constant fiber length such as was reported by Sanio for the Scots pine. Many more bordered pits were found in the spring than in the summer wood tracheids. The ends of the tracheids were frequently blunt or forked, though they are generally pointed in the summer wood. As a rule, the summer wood tracheids are shorter than the spring wood tracheids in all the material studied.

A rapid increase in all dimensions was found during the first 20 years of growth. The variation in length in a single tree was found to be from 0.8 to 7.65 mm. A direct relation was found to exist in the Douglas fir studied between the thickness of the cell walls of the summer wood and the strength of the material. In young wood, strength of material and thickness of wall were both low. No marked relation was found to exist between width of ring and fiber dimensions, nor was there any decline in the size of the elements due to age of the tree.

The Douglas fir and pine were not found to differ widely in the dimensions of their elements. Thickness of wall averaged higher in the longleaf pine, but the diameters were somewhat less than in the Douglas fir.

Permeability and viscosity, W. J. V. OSTERHOUT (Science, n. ser., 43 (1916), No. 1120, pp. 857-859).—Criticisms are given of the theory of Spaeth that the permeability of the surface layer of protoplasm is determined by its viscosity, which, in turn, depends on its colloidal condition.

Hail injury to cultivated plants, J. Weiger (Landw. Jahrb. Bayern, \$ (1913), No. 2, pp. 49-57).—This deals briefly with hail injury to maize, small grains, potatoes, beets, tobacco, vines, and fruit trees, with a few references to related contributions on this subject.

The injurious effect of tarvia fumes on vegetation, A. H. CHIVERS (Abs. in Science, n. ser., 43 (1916), No. 1106, pp. 363, 364).—An account is given of the destruction of a garden in Hanover, N. H., by fumes of a tar compound used on roads. The injury was found to be due to the constituents of the volatile substances, which condensed in the form of an oily coating on the surfaces of the plants, and did not involve to any extent the passage of gases through the stomata. The amout of injury was found to vary with the distance from the escaping fumes, the temperature of the melting tar, and the age of the plant structures.

### FIELD CROPS.

Irrigated pastures for northern reclamation projects, F. D. FARRELL (U. S. Dept. Agr., Bur. Plant Indus., Irrigated Pastures for Northern Reclamation Projects, 1916, pp. 16, figs. 2).—Based on experiments with irrigated pastures at several field stations and on observations made and information gathered on northern reclamation projects and in some of the other irrigated districts of the same region, directions are presented for the establishment and management of pastures under irrigation.

At the Huntley field station in Montana in 1914 and 1915, 2 cows were pastured each year for a season of approximately five months on three quarter-acre plats of mixed grasses and clovers. This represented a stock-carrying capacity of about 2.6 cows per acre. At the Gooding Experiment Station, Idaho, experiments conducted for three years showed the stock-carrying capacity per acre to be from 2 to 3 cows, 10 to 14 mature lambs, 10 to 12 ewes with their lambs, and 3 2-year-old steers per acre. At Huntley in 1915 a yearling heifer was placed on a quarter-acre plat of spring-seeded pasture on August 27 when the grasses average about 10 in. in height. The plat was divided into two parts which were grazed alternately and the heifer remained on the pasture for 58 days, the carrying capacity being rated at 4 yearlings per acre. At this farm the grazing periods on pasture plats averaged from 12 to 15 days.

In discussing the irrigation of pastures it is pointed out that at Gooding pastures were irrigated from nine to eleven times each year for three years, receiving from 2.48 to 2.73 acre-feet of water per acre each year. The quantity of water was no greater than was necessary for alfalfa though about 50 per cent more than needed for spring grains and potatoes. Decidedly beneficial effects were noted at the Huntley station from the application of a top-dressing of manure to 2-year-old pastures.

[Influence of the depth of plowing on yield], I. Kolesnikov (Zhur. Opytn. Agron., 15 (1914), No. 1, pp. 33, 34).—The Don Experiment Station, conducting experiments with different depths of plowing, observed that the greater yield was obtained in all cases by plowing about 9.5 in. deep, while plowing to a depth of only 3.5 in. brought a marked reduction. As compared with plowing 3.5 in. deep, the average yields for the past ten years showed an increase of 10.5 per cent for the depth of 9.5 in. and of 6.9 per cent for the depth of 7 in.

Grains for the Montana dry lands, N. C. Donaldson (U. S. Dept. Agr., Farmers' Bul. 749 (1916), pp. 22, figs. 11).—This bulletin presents information regarding the varieties of winter wheat, spring wheat, oats, barley, and flax adapted to the dry lands of Montana, and the best methods of growing them as indicated in part by the results of tests conducted for the past eight years at the Judith Basin Substation, Moccasin, Mont., in cooperation with the Montana Experiment Station.

The varieties regarded as best are Kharkof winter wheat, Pelissier durum wheat, Marquis spring wheat, Sixty-Day oats, White Smyrna barley, and Russian flax. It is recommended that winter wheat be sown at any time between August 10 and September 10 at the rate of 3 pk. per acre, and that spring wheat, oats, and barley be sown as early as the land can be prepared. The best time for sowing flax is given as April 15 to May 1. The rates of seeding for spring grain crops recommended are as follows: Wheat 4 pk. to the acre, oats 4 to 5 pk., hulled barley 5 pk., hull-less barley 4 pk., and flax 15 to 20 lbs. Summer fallowing is not recommended as a general practice, and the use of a cultivated crop such as corn is suggested as a substitute for fallow as grain seeded on disked corn ground yields nearly as well as grain on fallow. It is suggested that fall-plowed land be left rough to catch the snow and prevent the soil from blowing and that spring-plowed land for spring grain be worked down immediately after plowing.

Corn in Montana, A. Atkinson and M. L. Wilson (Montana Sta. Circ. 53 (1916), pp. 109-163, figs. 26).—This circular is made up of extracts from Bulletin 107 of the station, already noted (E. S. R., 35, p. 338).

Selecting and curing seed corn, A. Atkinson and M. L. Wilson (Montana Sta. Circ. 54 (1916), pp. 165-184, figs. 23).—This circular describes and discusses practical methods of field selection, drying, testing for germination, and preparing for planting of seed corn under Montana conditions and requirements.

The culture of jute in India and Indo-China, L. Hautefeuille (Bul. Econ. Indochine, n. ser., 18 (1915), Nos. 113, pp. 265-332; 114, pp. 490-534).—The jute industry in these regions, including production, commerce, and manufacture, is discussed from many different standpoints, and the results of cultural and fertilizer experiments conducted by the author and others during the past 10 to 15 years are briefly reviewed. The results of numerous fiber determinations of varieties of the two principal species, Corchorus capsularis and C. olitorius, are given in tables. Economic and sociological conditions as related to the jute industry are also considered.

[Serradella, with reference to economic value, inoculation, and development on light and heavy soils], B. Heinze (Naturvissenschaften, 3 (1915), Nos. 26, pp. 339-343; 27, pp. 352-355).—This article discusses the plant from historical, botanical, and cultural points of view and reports briefly the results of culture tests on heavy soil at Lauchstedt, together with those of analytical studies setting forth especially dry matter content and nitrogen production. The points considered are the appearance of the plant, its development, soil and climatic requirements, its uses in field, orchard, and garden, the importance of proper inoculation, soil preparation and fertilization, and diseases and insect enemies.

In the experiment reported the best results were secured where serradella was grown two years in succession. The plants there developed numerous nodules on their roots, were of dark green color, and produced two cuttings of one meter in height in addition to pasture, the two cuttings corresponding to 67,473 lbs. of green substance or 10,442 lbs. of air-dry material per acre. The roots are reported as containing 2.76 per cent and the stems and leaves 3.3 per cent of nitrogen. Where grown after mustard and on soil never having produced the crop, no nodules developed, the plants were of a light yellowish green color, and the nitrogen production per acre amounted to only 46.4 lbs. After lupines serradella grown on the land for the first time developed approximately as well as on the same kind of soil on which the crop had been grown before.

Pot experiments with manganese as a fertilizer for sugar beets, O. FALLADA and I. K. Greisenegger (Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 44 (1915), No. 5, pp. 379-388).—Manganese sulphate was applied at the rates of 25, 50, and 100 kg. per hectare (22.3 to 89 lbs. per acre), and manganese dioxid at the rates of 150, 300, and 600 kg. per hectare.

The use of 50 kg. of manganese sulphate and of 150 kg. of manganese dixoid per hectare gave the best general results. The check tests produced an average of 348.3 gm. of beets with 21.45 per cent of sugar in the juice, and a purity coefficient of 89.8 per cent. The tests in which 50 kg. of manganese sulphate was used gave 362.3 gm. of beets with 21.52 per cent of sugar and a purity of 92.2 per cent and the tests with 150 kg. of manganese dioxid yielded 367.3 gm. of beets containing 22.25 per cent of sugar with a purity of 93.3 per cent.

The sugar content of the beets did not appear to be influenced to a great extent through the application of these forms of manganese. The larger quantities applied apparently interfered with the growth of the plant, and reduced the yield of beets and sugar below the production of the check tests. The heavy applications reduced the growth of the leaves to a less extent than the development of the root, and also raised the water requirement of the plants as based on the production of organic matter or of sugar.

Methods of fertilizing sweet potatoes, C. E. Durst (Illinois Sta. Bull. 188 (1916), pp. 268-278, fig. 1).—This bulletin presents a report on fertilizer experiments with sweet potatoes conducted for five years in Union County on

eight plats, each one-thirty-third of an acre in size. A comparison was made of the use of 660 lbs. per acre of a home-mixed fertilizer consisting of 2 parts steamed bone, 2 parts dried blood, and 1 part potassium sulphate by weight; of 10.56 tons of manure; and of 528 lbs. of steamed bone; on two series of plats, on one of which the applications were made broadcast and on the other under the ridge upon which the sweet potato plants were placed.

The results indicated that each of the fertilizer treatments used increased the percentage of table potatoes produced and that, with the possible exception of the home-mixed fertilizer, higher percentages were secured when the fertilizer was applied under the ridge than when broadcasted. Each treatment also increased the total yield, the higher yields being secured from the fertilizer application made under the ridge. It was further indicated that only manure or steamed bone applied under the ridge is likely to give a material increase in the net value of the crop after deducting the cost of the fertilizer.

Studies of the timothy plant.—I, The influence of maturity upon the yield, composition, digestibility, palatability, and feeding value of timothy hay, H. J. Waters et al. (Missouri Sta. Research Bul. 19 (1915), pp. 2-68, figs. 37).—The results of these studies, in progress for some years, are reported. The data secured are given in tables and are also presented graphically.

In studying the effect of maturity on yield, the first cutting was made about June 12 when the plants were just in full head, the second about June 20 when the plants were in full bloom, the third about July 1 when the seeds were beginning to form, the fourth about July 8 when the seed was in the dough, and the fifth about July 16 when the seed was ripe but not shattered. The average of all trials in which cuttings were made showed the largest yield from the third cutting and, regarding the value of this cutting as 100, the relative value of the fourth cutting was 99.3, the second 93.8, the fifth 89.7, and the first 89.4. The first and last cuttings produced an average of between 500 and 600 lbs. less hay per acre than was secured from the third and fourth cuttings.

The digestibility of the hay was found to decline steadily as the plant developed, beginning as early as when the plants are in full head. The second cutting, when the plants were in full bloom, gave the largest yield of digestible dry matter, protein, fat, crude fiber, and nitrogen-free extract. Tests on the palatability of the hay showed that yearling steers subsisting entirely on hay and milk cows receiving grain and other roughage besides the hay preferred the first, second, and third cuttings, while sheep full fed on mixed grain apparently ate one cutting with as much relish as another.

It was further observed that early cutting tended to weaken the stand and late cutting to conserve the strength of the plant and to prolong its life. Studies relating to the permanence of stand indicated that "the thick, vigorous stand following late cutting does not result from the new plants that have sprung from seed left on the land at the time of harvest, but from the new plants which have come from the perfectly developed and well-filled bulbs at the base of the old timothy plants. It is from these bulbs that new plants for the next year's stand come. The bulbs reach their full development only when the plants are allowed to become mature before being harvested."

While the earlier cuttings gave larger yields and hay of higher digestibility and palatability, the later cuttings afforded greater convenience in harvesting, the weather conditions being generally more favorable and less time being required for curing. The late-cut as compared with the early-cut hay was much less liable to injury from rains and dews, from sunburn and under or over curing, and also turned water in the shock or stack much better.

The results of an investigation of the reproduction of the timothy plant are summarized as follows: "A seed sown in the fall or early spring produces a single plant. In the spring this plant produces a stalk and head. The head flowers and produces seed. A bulb at the base of the stalk enlarges as the stalk increases in height and, about the time the head appears, new shoots spring from the bulb and develop into small plants which are attached and clustered about the central plant. A root system will develop later on each of these new plants, all at the expense of the parent bulb. The parent bulb reaches its full development at about the time the main seed-bearing head is ripe or a little while before. The secondary plants may continue to grow and may produce heads and bear seed before the close of the growing season if the season is favorable and if left undisturbed. Bulbs and roots develop on these new plants largely at the expense of the parent bulbs, which by this time becomes shriveled and soon dies, having fulfilled its function. At the close of the growing season these secondary bulbs are well developed and have established their own root systems. They remain dormant through the winter; in the spring they send forth the stalks which later head, flower, and produce seed in the usual manner, so the process of regeneration of the previous year is repeated."

The advantages of clover over timothy in the rotation are pointed out.

Studies of the timothy plant.—II, The changes in the chemical composition of the timothy plant during growth and ripening, with a comparative study of the wheat plant, P. F. TROWBRIDGE, L. D. HAIGH, and C. R. MOULTON (Missouri Sta. Research Bul. 20 (1915), pp. 3-67, figs. 17).—Studies were made of the changes in the chemical composition of the entire timothy plant during growth and ripening as compared with similar changes in the wheat plant. The results are discussed at some length, a review of the literature being included, and the data are given in detail in tables and graphs. For the purpose of the investigation samples of the timothy plant were secured as follows: May 23, 1908, when the plants were about 1 ft. high in rapid growth with no heads showing, June 6 when no stalks were in bloom but were beginning to head, June 18 when in full bloom, June 30 when just out of bloom and the seed formed, July 9 when the seed was in the dough, July 20 when the seed was fully ripe, and March 16, 1909, when growth had not yet started but the plants were considerably green. The wheat plant samples were collected as follows: May 23, 1908, when the plants were green and in bloom, June 4 when the seed had formed and was in the milk, June 11 when the seed was in the dough, and June 19 when the seed was fully ripe.

It was found that the timothy plant took up nitrogen and ash constituents at the most rapid rate and contained the highest percentage and amount of moisture in the green plant during its earlier stages of growth. The absorption of plant food continued, but at a decreasing rate corresponding to the decreasing rate of growth, as it approached maturity. The heads increased in dry matter throughout the growing and ripening period. This increase included all the plant constituents except potassium oxid which had reached its maximum before the plants were in full bloom. Nitrogen-free extract increased at the greatest rate of all constituents and as the heads approached full ripening a noticeable increase in phosphorus pentoxid was observed.

The stalks and leaves increased in dry matter during growth and ripening, the dry matter added consisting chiefly of crude fiber and nitrogen-free extract. Nitrogen, ether-soluble material, potassium oxid, and phosphorus pentoxid increased during growth but decreased to some extent during ripening. The bulbs increased in dry matter throughout the growing period but the amount became constant before the ripening of the hay. The matter stored was principally

nitrogenous matter and nitrogen-free extract, no starch being produced in the bulbs during the storing process. Potassium oxid was found in maximum amount in the first stage, while phosphorus pentoxid showed a tendency to increase in amount as the plant matured. Approximately as many heads were produced at the full height as there were bulbs at the beginning of the season's growth. It was further observed that the plant above ground loses an absolute amount of dry matter from the time the seed is in the dough until it is fully ripe as the result of washing by rain and dew and a falling off of dead parts.

The wheat plant was found to resemble the timothy plant in taking up its nitrogenous and mineral matter and in containing the highest percentage of moisture in the green plant in the earlier stages of growth, and also in losing an absolute amount of dry matter at the time of full ripening due to washing by rain and dew and the falling of dead parts. The heads gained more uniformly and rapidly in their amount of dry matter than any other part. Nitrogen-free extract was found to be produced and stored at a greater rate than any other constituent but nitrogen, ash, and ether-soluble matter were added in some quantity also. The fiber was determined as practically all formed by the time the blossom has fallen and as remaining constant to ripening. The stalks and leaves contained their maximum amount of dry matter at blossoming time, after which nitrogenous material and nitrogen-free extract passed to the ripening heads.

The roots and stubble increased in dry matter up to the milk stage, after which a decrease took place as the dry matter passed to the portion of the plant above ground. The fiber present in the roots did not decrease in amount but nitrogenous and ether-soluble matter, ash, and nitrogen-free extract passed out of the roots into the growing plant above ground during the ripening of the heads.

In both wheat and timothy plants the percentage of protein, ash, and ether extract showed a tendency to reach a higher value in the young than in the mature plant, while the percentage of crude fiber and nitrogen-free extract was the greater at maturity.

Hilling of Voandzeia subterranea, P. C. VAN DEE WOLK (Cultura. 27 (1915), No. 328, pp. 405-417).—This article discusses the peanut and Voandzeia subterranea and brings out their common and individual characteristics. Considerable attention is given to subterranean fruit production which is common in both plants.

In an experiment conducted to test the effect of hilling, as is practiced in peanut culture, the Voandzeia plants all died as the result of this method of cultivation. The author points out that hilling among other disadvantages brings about conditions which favor disease attacks.

Comparative variety tests with squarehead winter wheat from 1908 to 1910, C. Leverenz (Arb. Deut. Landw. Gesell., No. 278 (1915), pp. XXVI+240+8, pls. 5).—This report presents at considerable length and in great detail the results of cooperative tests of nine varieties of squarehead winter wheat conducted throughout Germany during the three years 1908 to 1910. The principal varieties were Original Strube Schlanstedt, Original Strube Silesian, and Original Leutewitz.

A summary based on the results of all the tests showed that the Strube Schlanstedt variety yielded an average of 3,051 kg. of grain and 4,984 kg. of straw per hectare (2,715 lbs. and 4,436 lbs. per acre, respectively), Silesian 2,646 kg. of grain and 5,271 kg. of straw, and Leutewitz 3,001 kg. of grain and 5,018 kg. of straw. Of about 158 tests relating to grain yield and 132 to straw production, 97 of each raised no question regarding methods used or the results

obtained, and these taken by themselves showed higher yields in every case, but did not change the relative standing of the varieties. In the grain tests Strube Schlanstedt is stated to have ranked first 69 times and second 68 times, Silesian first 31 times and second 20 times, and Leutewitz first 60 times and second 71 times. For the three years Strube Schlanstedt gave an average 1,000-kernel weight of 38.24 gm., a liter weight of 764.3 gm., and a flintiness of 40.49 per cent; Strube Silesian a 1,000-kernel weight of 38.71 gm., a liter weight of 753.9 gm., and a flintiness of 30.14 per cent; and Leutewitz a 1,000-kernel weight of 38.16 gm., a liter weight of 763.9 gm., and a flintiness of 41.5 per cent.

Wheat culture in Argentina, C. D. Gibola (Bol. Min. Agr. [Buenos Aires], 19 (1915), No. 8-9, pp. 621-652, figs. 10).—This article is a continuation of material published in 1904 (E. S. R., 16, p. 663). The following varieties of wheat, regarded as new for Argentina, are described from historical, botanical, and cultural standpoints: Karachi, Delhi, Huasan Clubwheat, White Andalgalá, Spanish, Chileno, Violet, Smooth Russian, and Pampas. Of these varieties White Andalgalá is a club wheat, and Spanish, Chileno, and Violet are durum wheats, while the rest belong to the common bread wheats.

The value of good seed, C. R. ZAVITZ (Ann. Rpt. Live Stock Branch Ontario, 1914-15, pp. 73-76).—A popular article on the subject, in which are discussed the varieties of field crops and the quantities of seed giving the best results as determined in experiments and by observations made by the Ontario Agricultural College, the Ontario Agricultural and Experimental Union, and other agricultural organizations.

Seed tests made at the station during 1915, M. T. Munn (New York State Sta. Bul. 416 (1916), pp. 55-74; abridged ed., pp. 2).—The results of purity tests of samples of seeds collected are reported in tables and are briefly discussed.

Of 323 official samples of seed from dealers' stocks 4.6 per cent were found to be violations of the seed law. Samples from correspondents for testing the purity numbered 777, a decrease as compared with the previous year.

Samples of orchard grass showed in some cases intentional adulteration with chaff and inert matter, and samples of Dwarf Essex rape seed adulteration with cheap bird rape seed and other varieties of rape and various kinds of mustard seed. Dodder was found in one sample of orchard grass seed into which it had been intentionally introduced, and over 10 per cent of the alfalfa seed samples contained dodder, in one instance to the extent of 2.5 per cent.

Agricultural value of impermeable seeds, G. T. Harrington (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 20, pp. 761-796, pl. 1, figs. 6).—The results here reported are based on germination tests of lots of clover and alfalfa seed and a smaller number of such tests of winter vetch, okra, and other seeds, made to determine the agricultural value of seeds whose coats are impermeable to water at temperatures favorable for germination. It is pointed out that the cultivated species sometimes producing impermeable seeds include okra, alfilaria, atriplex, asparagus, morning-glory, canna, cherry-tomato, and nearly all of the cultivated species of Leguminosæ.

Commercial samples of 12 species of small-seeded legumes tested during the six years, 1904 to 1909, gave a range from 0.96 per cent of impermeable seeds in spring vetch to 71.67 per cent in spotted bur clover. The samples of white sweet clover, toothed bur clover, and yellow-flowered sickle lucern also contained high percentages of impermeable seeds. In a test of 128 lots of seed one to five years old and including red clover, alsike clover, white clover, sweet clover, alfalfa, hairy vetch, crimson clover, okra, Chamæcrista nicitans, and Robinia pseudacacia, over 90 per cent, and in most cases 100 per cent of the

impermeable seeds were viable except in the seed of *C. nicitans*. The average percentage of viability of the impermeable seeds was invariably greater than of the seeds which softened within six days.

In an experiment to determine the average rates of softening of seeds which had remained impermeable after ten days in wet blotters, less than 10 per cent of the seeds of red clover, alsike clover, white clover, and sweet clover softened in one month, and from about one-third to a little over one-half of them softened in three years when kept in wet blotters. Nearly all of the impermeable seeds of alfalfa, hairy vetch, okra, and crimson clover softened in one year, but a very few of all except crimson clover remained impermeable after three years.

In dry storage nearly all impermeable seeds of alsike clover, white clover, and sweet clover remained impermeable from two to three years. Impermeable red-clover seeds became permeable gradually in dry storage, but it was found that from one-third to two-thirds may still be impermeable after four years. Impermeable clover seeds thoroughly matured before harvesting as compared with similar seeds not so well matured softened and germinated more slowly under conditions favorable to germination and also became permeable more slowly in dry storage.

Among other methods of treatment reported it was found that alternations of temperature caused the softening and germination of many impermeable clover seeds when a temperature of 10° C. (50° F.) or cooler was used in alternation with a temperature of 20° or warmer. The effect of these alternations was greatly increased by previously exposing the seeds to germination conditions at 10° or cooler and was decreased by previously exposing the seeds to germination conditions at 30°.

Even under the most favorable conditions only a small proportion of impermeable seeds of red clover, alsike clover, white clover, and white sweet clover was found to produce seedlings promptly when sown in warm weather, and it was also observed that such seeds will pass the winter in the soil in a freezing climate without injury. The impermeable seeds of these species when placed in wet blotters softened and germinated more slowly than similar seeds of alfalfa, crimson clover, hairy vetch, and okra. All germinated within one year in some cases, while in others over 50 per cent were still impermeable after four years. It is stated that a large proportion of impermeable alfalfa, crimson clover, okra, and hairy vetch seeds will germinate in the soil during the first few months after planting, but that nearly all alfalfa and okra seeds, even if impermeable in the fall, are killed when they pass the winter in soil or on the plants out of doors in a freezing climate. Suggestions for the use of impermeable seeds are included.

#### HORTICULTURE.

The garden book, V. D. Davis (New York: Orange Judd Co., 1915, pp. VIII+244, pls. 7, figs. 47).—A popular treatise on the growing of vegetables under both home and market conditions.

The small garden, J. Schneider (Der Kleingarten. Leipsic and Berlin: B. G. Teubner, 1915, pp. 95, figs. 80).—A practical treatise on the propagation, culture, and care of fruits, vegetables, and flowers in the home garden, with special reference to German conditions.

The fruit growers' yearbook and market gardeners' guide, 1916 (London: The Cable Printing & Publishing Co., Ltd., 1916, pp. 172, figs. 9).—This yearbook contains a monthly working calendar for indoor and outdoor fruit growing in England, a review of the previous year's fruit and vegetable prices at Covent

Garden Market, and numerous miscellaneous articles dealing with the culture, care, and management of fruit under British conditions.

[Report of horticultural investigations], R. S. Seton (*Univ. Leeds and Yorkshire Council, Agr. Ed.* [Pamphlet] 96 (1915), pp. 50-56, fig. 1).—Fertilizer tests with strawberries as well as variety tests with potatoes, bush fruits, raspberries, and strawberries being conducted under the direction of the University of Leeds are reported. An experiment being conducted with various lawn mixtures is also outlined.

Methods used in the propagation of plants, T. D. Hatfield (*Trans. Mass. Hort. Soc.*, 1916, pt. 1, pp. 89-102).—In this paper the author discusses the different methods of propagation and their application in the propagation of various classes of plants.

Greenhouse heating (New York: A. T. De La Mare Printing & Publishing Co., Ltd., 1916, pp. 52, figs. 2).—This comprises a reprint of four prize essays which recently appeared in the columns of The Florists' Exchange. A digest of the essays, together with comments by J. McArthur and a collection of answers to questions on greenhouse heating, is also included.

Culture and forcing of Witloof chicory, J. W. Wellington (New York State Sta. Bul. 418 (1916), pp. 89-98, pls. 3).—As a result of some forcing experiments conducted at the station it is believed that Witloof chicory deserves much greater attention at the hands of home gardeners and that at present prices it can not fail to give good financial returns to market gardeners.

This bulletin discusses the importance of Witloof chicory in Europe, its culture and varieties, and describes in detail the cultural methods employed at the station. The plants were easily grown from seed, and sand proved to be a very satisfactory medium with which to cover the forcing roots. It blanches the leaves perfectly and promotes the formation of compact heads. Roots having a crown diameter within the limits of 1 to 2 in. produced the greater number of marketable heads. Temperatures ranging from 50 to 60° F. appear to give optimum conditions for producing a marketable crop.

Witloof chicory, F. H. Hall (New York State Sta. Bul. 418, popular ed. (1916), pp. 4, pls. 2).—A popular edition of the above.

Transmission of resistance and susceptibility to blossom-end rot in tomatoes, H. P. Stuckey (Georgia Sta. Bul. 121 (1916), pp. 83-91 figs. 3).—In previous work at the station it was found that the cherry, pear, and currant-tomatoes were immune to the blossom-end rot (E. S. R., 26, p. 648). This bulletin gives the results of crosses between the cherry type and a commercial variety, with special reference to the transmission of resistance and susceptibility to the blossom-end rot.

The work indicates that both resistance and susceptibility are transmitted from parent to progeny. The fruit of the  $F_1$  progeny of the cross between Red Cherry (Lycopersicum cerasiforme) and the variety Greater Baltimore (L. esculentum) was resistant to the blossom-end rot and was intermediate in size and number of locules between the two parents, but tending toward that of the cherry type. The  $F_2$  progeny was likewise resistant to the blossom-end rot and varied widely in size of fruit and number of locules. At the same time no distinct Mendelian segregation of these two characters was observed.

Data are given showing the yield of a number of standard varieties and their susceptibility to the blossom-end rot. The immune varieties were either very early maturing or possessed cherry tomato blood. The Hybrid variety, the plants of which are the first generation progeny of the cross between the Red Cherry and Greater Baltimore, gave the highest yield of all the varieties,

this agreeing with the results obtained at the New York State Station relative to high yields from first generation hybrid tomato plants (E. S. R., 27, p. 239).

The control of fruit pests and diseases, A. L. MELANDER and F. D. HEALD (Washington Sta. Popular Bul. 100 (1916), pp. 5-61).—This describes the more important insect and animal pests and diseases of fruits and gives directions for their control, including information relative to the preparation of insecticides and fungicides.

Piping system for orchard spraying, G. P. Weldon (Mo. Bul Com. Hort. Cal., 5 (1916), No. 8, pp. 273-277, figs. 3).—A descriptive account with illustrations is given of an underground orchard piping system which was laid out in a California orchard for use in spraying the orchard.

The development of fruits for special conditions, W. T. Macoun (Trans. Mass. Hort. Soc., 1916, pt. 1, pp. 39-57).—A review of American activities in the development of hardy fruits, including suggestions for further breeding along this line.

Pollinating fruit trees, L. G. CORRIE (Jour. Heredity, 7 (1916), No. 8, pp. 365-369, fig. 1).—In this paper the author discusses various problems connected with the failure of trees to set a crop, and summarizes the results of some long-continued pollination trials conducted at the John Innes Horticultural Institution at Merton, Surrey, England.

The newer fruits in 1915 and how secured, N. E. Hansen (Minn. Hort., 44 (1916), No. 8, pp. 307-312, figs. 2).—In this paper the author notes the propagation in 1915 of two new plums that have borne several excellent crops, and summarizes his recent endeavors in the line of breeding pears resistant to both cold and blight.

Two hardy species of pears, *Pyrus ovoidea* and the birch-leaved pear (*P. betulifolia*), have been hybridized with many of the best cultivated pears of Europe and have been distributed for testing purposes.

The cherries of Japan, E. H. Wilson (Pubs. Arnold Arboretum, No. 7, Sup. (1916), pp. III).—In view of the appearance of Miyoshi's work on the cherries of Japan (E. S. R., 25, p. 645), which antedated the author's work (E. S. R., 35, p. 343) but was not received in time for consultation, the author here presents a supplement to his work containing a number of changes in nomenclature made to conform to the nomenclature of Miyoshi.

Harvesting and packing peaches, W. B. Lanham (Agr. and Mech. Col. Tex. Ext. Bul. B-22 (1916), pp. 8, figs. 8).—Practical directions are given for picking, grading, and packing peaches, with special reference to the use of the Georgia carrier.

Pyronia, L. Trabut (Jour. Heredity, 7 (1916), No. 9, pp. 416-419, figs. 2).— The pyronia (Cydonia veitchii), a hybrid which is said to be the first between the pear and quince, is here described and illustrated. The tree, which is growing at the botanic garden in Algeria, produces an abundance of seedless fruit of some value. The possibilities to plant breeders of using these two species for breeding other desirable fruits are pointed out.

The marketing of New York State peaches (New York: New York Central Lines, 1916, pp. 16, figs. 9).—The purpose of this pamphlet is to present definite information to peach growers and shippers of western New York relative to methods of marketing and distribution. The subject matter is based upon the shipping records of the New York Central and Hudson River Railroad Co. and information compiled from the 1915 Market News Letters of the Office of Markets and Rural Organization of the U. S. Department of Agriculture. Methods of improvement in the marketing of the 1916 peach crop are herein outlined.

Some notes on the breeding of raspberries, R. D. Anthony (New York State Sta. Bul. 417 (1916), pp. 75-88, pls. 8).—The author briefly reviews the earlier work in the breeding of raspberries at the station and discusses in more detail the results of crosses begun with the red, black, and purple raspberries in 1910.

The investigations have shown beyond doubt that the purple raspberries do not belong to a distinct species but have originated as hybrids of the blackcap and the red raspberry. Some very promising seedlings of these have been secured. The work shows that improved purple varieties are more apt to be developed by crossing reds and blacks than by selecting from the existing purple varieties. Pure seedlings of the purple raspberry Columbian, an  $F_1$  hybrid, failed to break up as much as would be expected in the  $F_2$  generation. None showed any tendency to propagate by suckers, nor did any have fruit of the color of either parent. In cane color and glaucousness some of the seedlings approached more nearly the parent types. Hybrid seedlings were produced by crossing two blackcaps with a red raspberry. With one cross the seedlings were all purple. Among the 289 seedlings of the other cross were ten yellows.

Performance records are given for several varieties of raspberries which were studied with reference to their desirability as breeding parents. A study of the inheritance of color of fruit indicates that several of the black raspberries are heterozygous for color and that probably several color factors are present. The same thing holds with the red raspberry though the higher number of yellows present would indicate fewer color factors. Glaucousness is considered a dominant character. Likewise rough bark is dominant to smooth bark. The factor for dwarfing appeared to be of rather rare occurrence.

Three of the seedlings of the purple raspberry Columbian produced some unusual abnormalities in the flower cluster, including gradations from perfect fruits to those in which the drupelets were replaced by small, sepal-like leaves, also fruits varying from perfect to entirely sterile forms which did not have the leafy growth. From a correlation which was found between leaf coloration and fruit it appears possible to tell all yellow raspberries from either the red or purple sorts by the absence of any tinge of red on the leaves. It is suggested that the bark of the young canes of the yellow varieties is also probably entirely lacking in any touch of red or purple color.

Notes are given on some crosses made between the flowering raspberry (*Rubus odoratus*) and the red raspberry, blackberry, and the dewberry. Of these crosses only those made with the Herbert red raspberry were brought to the blooming period.

Breeding raspberries, F. H. Hall (New York State Sta. Bul. 417, popular ed. (1916), pp. 4, fig. 1).—A popular edition of the above.

Notes on viticulture and enology, N. García de los Salmones (Apuntes de Viticultura y Enologia. Pamplona, Spain: Author, 1915, pp. 929).—The present work has been prepared as a text-book on viticulture and enology for use in the agricultural courses of the provincial school of Navarra, Spain, as well as a manual of information on the subjects for vineyardists and wine makers.

Some history of the grape in the United States, G. C. Husmann (*Trans. Mass. Hort. Soc.*, 1916, pt. 1, pp. 59-70).—A brief historical review of the grape and wine industry in the United States.

Statistics on the production of grapes and olives in 1915 (Estadistica de las Producciones Viticola y Olivarera en el Año 1915. Madrid: Govt., 1916, pp. 9).—A statistical report on the production of grapes, wine, olives, and olive oil in various regions and Provinces of Spain during the year 1915.

Taming the wild blueberry, F. V. Coville (Trans. Mass. Hort. Soc., 1916, pt. 1, pp. 103-123).—The substance of this paper is contained in the author's bulle-

tin on blueberry culture (E. S. R., 34, p. 534) and the article previously noted (E. S. R., 35, p. 647).

The effect of organic matter on citrus growth, J. F. Breazeale (Cal. Citrogr., 1 (1916), No. 11, pp. 7, 19, figs. 3).—By way of summing up the evidence relative to the mosaic disease or mottling of citrus fruits, the author states that practically all investigators at the present time agree that mottling is one of the so-called soil troubles. The experience of the author, working with citrus water cultures and pot cultures, shows that an application of soluble organic matter, the so-called humus extracted from peat, decomposed alfalfa, and the like, even in minute amounts, 5 or 10 parts per million, will bring about a decidedly stimulating effect upon the citrus seedlings. These results, considered in connection with the soil types of the Riverside citrus area, led him to conclude that mottling may be rightly called malnutrition. It can be traced back to the root tip and is undoubtedly influenced in a large measure by the scarcity of organic matter in the soil.

California grapefruit, A. D. SHAMEL (Mo. Bul. Com. Hort. Cul., 5 (1916), No. 7, pp. 289-249, figs. 4).—This paper has been previously noted under another title (E. S. R., 34, p. 835).

Notes on coffee in Java, P. J. Wester (*Philippine Agr. Rev.* [English Ed.], 9 (1916), No. 2, pp. 120-132, pls. 7).—This comprises extracts from a report to the Philippine Bureau of Agriculture on the coffee industry in Java and deals particularly with the kinds of coffee and the process of preparing coffee for market. Data on the cost of production are also given.

The germination of tea seed, C. Bernard (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 43 (1915), pp. 30-88, pls. 6).—In this paper the author describes the germination process of tea seed, and gives the results of some germination tests in which the seeds were sown with and without the hard shell, placed with the eye in different positions, and grown under different strengths of light.

The selection of the tea plant, III, P. van Leersum and C. Bernard (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, No. 43 (1915), pp. 1-29, pls. 3).—This comprises a further report on experiments being conducted by the authors with the special object of developing through selection a race of tea better adapted to conditions in Java than the present forms (E. S. R., 30, p. 444). The results secured from germination tests of selected strains of seed are reported, and suggestions are given for conducting selection experiments.

Experience in top-working hickories, F. B. Guinn (Amer. Fruits, 24 (1916), No. 2, p. 27).—In this paper the author gives a brief account of his experience in top-working hickory trees with different varieties of pecans.

How to make a flower garden (Harrisburg, Pa.: The Countryside Press, 1915, pp. 75, figs. 15).—A small practical treatise.

Peonies, J. H. Sperry (Country Gent., 81 (1916), No. 34, pp. 1556. 1557, figs. 3).—In this article the author discusses the general cultural treatment of peonies and gives a descriptive list of some of the best varieties of herbaceous Chinese peonies as observed during the season of 1916.

Roses of Denmark, S. Almquist (Bot. Tidsskr., 34 (1916), No. 6, pp. 257-287).—An account of the rose flora of Denmark, including a classification of

types and descriptions of species.

The white-barked pine, D. F. Higgins (Jour. Heredity, 7 (1916), No. 9, pp. 399-401, flgs. 2).—A brief descriptive account and illustrations are given of the white-barked (Pinus bungeana), which is grown in China as an ornamental and has been introduced into the United States for trial by the U. S. Department of Agriculture.

Practical landscape gardening, R. B. CRIDLAND (New York: A. T. De La Mare Printing & Publishing Co., Ltd., 1916, pp. 266, pl. 1, figs. 189).—This work discusses the importance of careful planning; locating the house; arrangement of walks, drives, and entrances; construction of walks and drives; lawn making; ornamental planting of trees, shrubs, and flowers; architectural features of the garden; hardy borders; rose gardens; and wild gardens. Planting plans and planting keys are also included.

National system of highways and landscape designing, C. Kehr (U. S. Senate, 64. Cong., 1. Sess., Doc. 350 (1916), pp. 12).—An address delivered before the American Civic Association at Washington, D. C., on December 31, 1915, in which the author advocates a nation-wide system of highways, affording communication between major centers, which will not only be direct but will combine landscape effects with utility.

Garden writings in America, L. Barron (*Trans. Mass. Hort. Soc.*, 1916, pt. 1, pp. 71-88).—In this paper the author reviews the trend of contemporary American garden writings and publications, with special reference to their adaptability to gardening conditions in America.

#### FORESTRY.

Suggestions as to possibilities of silviculture in America, B. E. Fernow (*Proc. Soc. Amer. Foresters, 11 (1916), No. 2, pp. 171-176)*.—In this paper the author discusses the various factors which may influence the practice of silviculture in this country, and calls attention to the need of securing a more thorough knowledge relative to the principles of silviculture as applied to America.

The woodlot: Its present problems and probable future status in the United States, C. R. Tillotson (*Proc. Soc. Amer. Foresters, 11 (1916), No. 2, pp. 198–207*).—In this paper the author confines his discussion of the present woodlot problems to those which exist in the prairie and in the older settled, formerly timbered agricultural region of the Central States. The probable future status of the farm woodlot in the United States is also considered.

Forest taxation as a factor in forest management, G. W. Hutton and E. E. Harpman (*Proc. Soc. Amer. Foresters, 11 (1916), No. 3, pp. 330-335*).—The present paper is based on a study of present tax methods in the State of Washington.

Hewn-tie versus saw-timber rotations, C. F. Korstian (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 3, pp. 315-329).—In this paper the author presents the results of a detailed study of the Rio Pueblo and Rio Santa Barbara watersheds of the Santa Fe National Forest. The object was to determine the class of product, rotation, and cutting cycle to be used in the future silvicultural management of these and similar areas. It is concluded in substance that economic conditions in these areas warrant the use of a short rotation sufficient for the production of hewn ties rather than a long rotation for the production of saw timber. A short rotation is also considered more desirable from the pathological standpoint.

Christmas tree plantations, A. K. CHITTENDEN (Michigan Sta. Spec. Bul. 78 (1916), pp. 3-8, figs. 3).—The results secured from an experimental Christmas tree plantation established by the department of forestry of the station in 1909 are reported.

The area devoted to the experiment was 0.28 of an acre. Four-year-old Norway spruce transplants were used, the trees being spaced 3 ft. apart in triangles at the rate of 5,584 trees to the acre. Tree removals were begun in 1913, when the largest trees were taken out. During this period the loss in area was

less than 2 per cent. From 1913 to 1915, inclusive, 750 trees were taken out, all of which could be disposed of to good advantage, and 800 trees were left for future sale.

With these growth rates as a basis estimates are given showing the probable cost and returns from such a plantation. Assuming an average price of 15 cts, per tree with a 5-year rotation the gross returns for 5,305 trees amount to \$795.75. The cost of stock and planting plus 6 per cent for five years would be \$165.94, leaving a net balance of \$629.81. No allowance was made for occasional cultivations or harvesting, which is done during the winter months when work is slack. The experiment as a whole indicates that Christmas trees may be grown with profit as a farm crop in limited quantities, depending on the local demand and prices.

Hylobius pales as a factor in the reproduction of conifers in New England, E. E. Carter (Proc. Soc. Amer. Foresters, 11 (1916), No. 3, pp. 297-307, figs. 2).—Observations made by the author on various coniferous plantations in New England led to the conclusion that it is a waste of money to plant cutover pine lands during the first two seasons after cutting if the conifers most commonly planted in New England are used. Such plantations will be subject to heavy loss, in some cases amounting to almost complete destruction, by the beetle H. pales. This conclusion is in accordance with the practice in many parts of Europe, although the species and even the genera of both trees and insects are different from those in New England. It is suggested that if the advance growth of pine found in pastures or fields can not be removed two or more years in advance of making a coniferous planting on the land it would be better to leave the advance growth and make early thinnings to prevent the development of wolf trees.

The presence of this beetle adds to the difficulty of reproduction by the shelterwood method, inasmuch as the final cutting after the pine reproduction has started merely invites the destruction of the small trees by the beetles. If the strip method of reproduction is used, the intervals between the cutting of strips should be sufficiently long for the reproduction to have reached a height of 3 ft. or more before the timber on the next strip is cut.

Water requirements and growth of young cypress, W. R. Mattoon (*Proc. Soc. Amer. Foresters, 11* (1916), No. 2, pp. 192–197, figs. 3).—Some experimental tests made with cypress seed and seedlings are reported.

The results indicate in general that in the early stages both the seeds and seedlings of cypress demand a very high degree of soil moisture, so that in its juvenile stages the species seems to be semiaquatic in habit. From these results it is recommended that cypress seed be soaked for a period of several weeks, probably from four to eight, preparatory to sowing, thus reducing the cost of starting the seedlings as compared with the usual method of frequent waterings in nursery beds continued for a period of from one to three months.

The various osiers cultivated in France and neighboring countries, E. G. CAMUS (Vie Agr. et Rurale, 6 (1916), No. 32, pp. 95-98, figs. 7).—The different species and varieties of willows used in osier culture in France and neighboring countries are described.

The early European history and the botanical name of the tree of heaven, Ailanthus altissima, W. T. Swingle (Jour. Wash. Acad. Sci., 6 (1916), No. 14, pp. 490-498).—A brief review of the literature relative to the Ailanthus in Europe, together with notes on its introduction into the United States and its importance as an ornamental and economic tree.

The English names of some trees, W. W. ASHE (Proc. Soc. Amer. Foresters, 11 (1916), No. 2, pp. 233-239).—In this paper the author calls attention to the

confusion in the use of English names for many of our trees and suggests the use of certain names for correcting this confusion to some extent.

A forest census of Alabama by geographical divisions, R. M. Harper (*Proc. Soc. Amer. Foresters, 11* (1916), No. 2, pp. 208-214, fig. 1).—In the present paper the author divides the State of Alabama into ten geographical divisions, and gives a table showing for each of the ten regions and for the whole State the percentage of forests in 1910, the expenditure for fertilizer in 1909 per acre of improved land, the percentage of evergreens, and the percentage of the present forest made up by each species of tree.

Forests of Crater Lake National Park, J. F. Pernot (U. S. Dept. Int., Off. Sec. [Pub.], 1916, pp. 39, figs. 25).—A general account of the forest types in the

Crater Lake National Park, including descriptions of forest species.

The administrative report of the Virginia state forester from March to December, 1915, inclusive, R. C. Jones (Admin. Rpt. Va. State Forester, 1 (1915), pp. 48, figs. 8).—A summary of activities for the above period, together with suggestions for extending the state forestry work and recommendations for amendments to the present forestry laws.

The growing stock as a criterion of normality, A. B. RECKNAGEL (Proc. Soc. Amer. Foresters, 11 (1916), No. 3, pp. 308-314, fig. 1).—A brief comparison of

methods of determining the normal growing stock in forests.

Top diameters as affecting the frustum form factor for longleaf pine, H. H. Chapman (*Proc. Soc. Amer. Foresters, 11 (1916), No. 2, pp. 185-191*).—A further discussion relative to the application of the frustum form factor method of constructing volume tables for different species of trees (E. S. R., 34, p. 641), including the results of some tests of the form factor method on longleaf pine in Alabama.

The factor of top diameters in construction and application of volume tables based on log lengths, H. H. Chapman (Proc. Soc. Amer. Foresters, 11 (1916), No. 2, pp. 221-225).—In this paper the author calls attention to the errors which are apt to be made in connection with the use of the top diameter in the construction and application of volume tables based on log lengths.

The Biltmore stick and the point of diameter measurements, D. BRUCE (*Proc. Soc. Amer. Foresters, 11 (1916), No. 2, pp. 226-229)*.—The author here presents data to show the extent of error which may arise in using the Biltmore stick (E. S. R., 25, p. 843; 31, p. 341) by taking the measurements at the wrong height.

Utilization of wood waste by chemical means, H. F. Weiss (*Proc. Soc. Amer. Foresters*, 11 (1916), No. 2, pp. 177-184).—In this paper the author briefly describes the chemical processes now established in the United States which utilize wood waste, gives the extent to which they are now commercially established, and discusses their future outlook for expansion.

## DISEASES OF PLANTS.

[Plant diseases in Porto Rico], J. A. STEVENSON (Rpt. Bd. Comrs. Agr. P. R., 4 (1914-15), pp 33-44).—This is a report of the pathologist covering the period from July 1, 1914, to June 30, 1915.

Citrus scab, ascribed most commonly to Cladosporium citri, has begun to attack grapefruit. Fruit rot, or mal di gomma, seems to be on the wane at present. A Fusarium, as yet undetermined as to species and parasitic character, has been found present in typical fruit rot cases, but proper drainage and use of stocks other than lemon are expected to eradicate the disease. Fruit rots causing considerable loss during the season are ascribed to such fungi as Penicillium spp. Rhizopus nigricans, Aspergillus niger, and Diplodia

natalensis. Blossom-end rot of oranges may be due to a Fusarium. A black rot, ascribed to Alternaria citri, is not regarded as of very great importance at this time. Citrus canker is not yet known to have been brought to Porto Rico from the neighboring mainland.

Cytospora sacchari is a comparatively new disease of sugar cane, the well marked symptoms of which are briefly described. Root disease of sugar cane is a trouble ascribed to a number of organisms readily attacking the native cane. All the organisms yield to the same treatment.

A mold of cigars was found to yield Aspergillus sp. (a blue-green form), A. flavus, Cladosporium herbarum, Penicillium sp., and Fusarium sp., all probably saprophytic in the material used to fasten the wrapper.

Prickly pear near the southern coast is attacked by a fungus, apparently Diplodia opuntia.

Leaf spot (Cercospora citrullina) of watermelon was noted near San Juan.

A defoliating leaf spot of cowpeas is referred to C. vignæ.

Parasitic Rhizoctonias in America, G. L. Peltier (Illinois Sta. Bul. 189 (1916), pp. 281-390, figs. 23; abs., pp. 4).—In connection with a serious stem rot of carnations due to Rhizoctonia, the author has conducted an investigation of the diseases of vegetable, field, and floricultural crops which are caused by Rhizoctonia, the primary object being to determine whether infection is brought about by one or more than one species of Rhizoctonia.

It is stated that there are recognized in America two species of truly parasitic Rhizoctonia, *R. solani*, which is widely distributed on a great number of hosts, and *R. crocorum*, which is at present limited in its distribution to alfalfa and potato tubers. A third species, *Corticium ochroleucum*, is found on leaves of pomaceous fruit trees, while a fourth species, isolated from damped-off onion plants, is considered of questionable parasitism.

So far, the author has found that about 165 species of plants have been listed as subject to attack by *R. solani*. This list includes most floricultural plants, vegetable and field crops, herbaceous plants, and many weeds. From inoculation experiments conducted with a large number of types of plants, the author concludes that all the strains studied can be included under the one form *R. solani*. These investigations show that the virulence of *R. solani* is very variable, as is also the degree of resistance of the various host plants. No marked specialization was noted in any of the strains of the fungus. A certain vigor of mycelium was found to be required before *R. solani* is able to attack the plant. A high temperature (88° F.), together with too little or too much moisture determines to a large degree the virulence of the different strains. This fungus is said to become a dangerous parasite only under certain conditions.

An extensive bibliography is given.

The susceptibility of grains to smuts and rusts, O. von Kirchner (Fühling's Landw. Ztg., 65 (1916), Nos. 1, pp. 1-27; 2, pp. 41-72; 3-4, pp. 92-137).—The results of tests with a very large number of varieties of different agricultural grains are detailed and tabulated as regards their susceptibility to rusts and smuts with a discussion of the various factors predisposing to attack. A bibliography is appended.

Resistance of wheat to rust, O. Comes (Ann. R. Scuola Sup. Agr. Portici, 2. ser., 12 (1914), pp. 419-473).—This statement deals with rusts and other parasitic injury to wheat as related to stock, breeding, locality, soil, seeding time, and sap constitution.

Treatment of winter wheat against Fusarium, Penicillium, and stinking smut, L. HILTNER (Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 13 (1915), Nos. 8,

pp. 97-109, fig. 1; 9, pp. 113-124).—This continuation and conclusion of the report previously noted (E. S. R., 35, p. 651) records the results of work done in different localities during several years in testing winter wheat and rye as to the protective capability of several standard or commercial fungicides from which benefit was obtained.

Green vitriol (ferrous sulphate) as a preventive of take-all, G. P. DARNELL-SMITH (Agr. Gaz. N. S. Wales, 27 (1916), No. 2, p. 134).—It is stated that a considerable amount of loss was caused last season to the wheat crops of New South Wales by take-all, due to Ophiobolus graminis attacking the roots.

Of the various remedies tried, the application of ferrous sulphate to the soil has given partial success, and it is recommended as a result of experiments that it be tested further at the rate of about 50 lbs. per acre. It is claimed that ferrous sulphate oxidizes the organic matter of humus, hastening its decomposition, that it fixes ammonia in the soil, that it aids the plant in absorbing phosphoric acid from the soil, and that even at nonfungicidal strengths it imparts vigor to the plant, enabling it to resist soil parasites.

Storage rots of economic aroids, L. L. Harter (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 15, pp. 549-572, pls. 3, fig. 1).—A report is given of a study of storage rots of a number of species and varieties of Colocasia, Alocasia, and Xanthosoma. These plants suffer in storage attacks of a number of rots, and in 1912 several organisms were isolated from diseased material and subsequent inoculation experiments were carried on with the organisms.

Four storage rots are described, Java black rot, found to be caused by Diplodia tubericola, D. macluræ, D. gossypina, and Diplodia pp. from Mangifera indica; a powdery gray rot caused by Fusarium solani; Sclerotium rot caused by S. rolfsii; and soft rot caused by Bacillus carotovorus. All the organisms are wound parasites, and their parasitism was established by inoculation experiments. Relatively dry conditions favor attack by the Java black rot organism, while moisture was required for successful infection by the other organisms. High temperatures were more favorable to attack than low temperatures, B. carotovorus alone producing decay at an average temperature below 9° C. (48.2° F.).

Beets attacked by Cercospora beticola, E. Saillard (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 1, pp. 47-49).—Sugar beets were visibly injured during 1915 by the presence of C. beticola, which was recorded from several regions in France. The crop was reduced both in quantity and in quality as regards sugar content and the presence of nitrogen compounds. In some ways the anomalies observed were similar to those noted for the dry year 1911. Tabulated results for 1907 and for 1909 to 1912 are given and for 1915 in greater detail.

New diseases of cucumber in Sweden, J. Eriksson (Centbl. Bakt. [etc.], 2. Abt., 44 (1915), No. 1-4, pp. 116-128, figs. 10; abs. in Rev. Gén. Bot., 27 (1915), No. 323, p. 351).—A further account (E. S. R., 32, p. 641) is given of the history of the three fungi Cladosporium cucumerinum, Cercospora melonis, and Colletotrichum lagenarium.

Conditions favoring attack on cucumber by these fungi include breeding methods which produce weak or susceptible plants, and close and intensive culture, preventing the maintenance of hygienic conditions. Propagation is thought to occur possibly through the seedlings, involving a mycoplasm and a plasma stage similar to that claimed to be concerned in rust of cereals and mallows. Recommendations for control include frequent washings, aeration and soil renewal in the hot house, and the destruction of all plants not known to be free from infection.

Experiments with clean seed and potatoes on new land in southern Idaho, O. A. Pratt (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 15, pp. 573-575).—In connection with investigations of potato diseases in southern Idaho, where the crop is grown under irrigation, the author had a chance to test the belief that newly reclaimed lands offer an opportunity for the production of disease-free potatoes. In this region the diseases most prevalent are wilt, due to Fusarium oxysporum; black rot, due to F. radicicola; jelly end rot, due to Fusarium sp.; Rhizoctonia disease; a powdery dry rot, due to F. trichothecioides; and common scab.

A preliminary report is given of experiments conducted in the spring of 1915 to determine whether, by planting disease-free seed on new land, a disease-free crop would be obtained. Plats on virgin soil as well as on land where alfalfa or grain had been grown for several years were planted, and at harvest time a number of tubers were examined.

The presence of disease in the plats in which grain or alfalfa had been previously grown was considerably less than the percentage of diseased tubers obtained on plats of recently reclaimed desert land. Planting clean seed potatoes on new land did not guarantee a disease-free product.

The disease of potatoes known as "leak," L. A. HAWKINS (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 17, pp. 627-640, pl. 1, fig. 1).—An account is given of an investigation, carried on in the delta region in the San Joaquin Valley of California, of the tuber rot of potato known as potato leak, which was formerly reported as due to Rhizopus nigricans (E. S. R., 20, p. 948). The investigations of the author corroborate the work previously described in part. However, another fungus was obtained 49 times out of 61 attempts, and a study made of this proved it to be Pythium debaryanum. Inoculation experiments with this organism produced a rot identical to all appearances with potato leak, and it is considered probable that this disease is produced by both R. nigricans and P. debaryanum, the latter being apparently more frequently the causal organism.

Infection is believed to take place in the field from infected soil getting into wounds made in digging, as no infection was observed in the field or in the laboratory where the skin of the tuber was unbroken. From the results of these experiments, it is believed that the disease may be controlled by more care in harvesting and handling the potatoes and the careful sorting out of wounded tubers.

Some properties of the virus of the mosaic disease of tobacco, H. A. Allard (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 17, pp. 649-674, pl. 1).—In continuation of previous work (E. S. R., 30, p. 450), the author has described additional investigations on the virus of the mosaic disease of tobacco.

Evidence is presented to show that the infective principle can not be identified with peroxidase. The author claims that neither peroxidase nor catalase in the sap of diseased plants can be responsible for the mosaic disease. These enzyms are normally present in healthy plants, while the sap of such plants is without infectious properties. By evaporation of the enzyms present in healthy sap they may be brought to a high concentration, but such solutions never acquire infectious properties. On the other hand, the peroxidase content of mosaic sap may be diminished to such an extent that peroxidase reactions are no longer discernable, yet such solutions may remain highly infectious.

The author claims that neither enzyms nor any other normal constituent present in healthy sap is responsible for this disease, but that it is due to a particulate substance that is not a constituent of healthy plants. This pathogenic agent is highly infectious and is capable of increasing indefinitely within

susceptible plants, and, in the author's opinion, there is reason to believe that it is an ultramicroscopic parasite of some kind.

Mosaic disease of tobacco and tomatoes (Gard. Chron., 3. ser., 59 (1916), No. 1526, pp. 172, 173).—This is a discussion of the report of Clinton regarding calico disease of solanaceous plants (E. S. R., 34, p. 52).

Armillaria mellea killing fruit trees (Agr. Gaz. N. S. Wales, 27 (1916), No. 1, p. 16).—It is stated that a disease killing apple, peach, nectarine, plum, and other fruit trees has been found by E. Mackinnon to be caused by the honey fungus, A. mellea, previously noted (E. S. R., 33, p. 149) in connection with citrus trees.

If the parasite is found on the roots in the form of brown strands, all dead portions should be removed and the diseased areas scraped and treated with strong Bordeaux paste, made up of copper sulphate 1.5 lbs., quick lime 1 lb., and water 2 gal., and applied with a brush. Wounds should be dressed with Stockholm tar and the lower trunk and adjacent roots left exposed to the air from three to four weeks.

Spraying experiments and apple diseases in 1915, W. J. Mobbe (Maine Sta. Bul. 252 (1916), pp. 167-192, pls. 2).—This bulletin gives an account of apple spraying experiments carried on for the prevention of apple scab, describes winter injury to trees set in dynamited holes, and discusses two apple-leaf troubles, chlorosis and silver leaf, which are said to be new in Maine, and the overwintering of the apple-scab fungus on apple twigs.

The work on spraying is in continuation of a series of experiments which have been in progress for a number of years, and a summary of the results has already been given (E. S. R., 35, p. 549). In 1915, the scab developed to such a slight extent on the experimental plats even where no spray was applied that the results are considered less conclusive than in previous years. The application of Bordeaux mixture in connection with arsenate of lead resulted in considerable russeting of the fruit. The highest percentages of perfect apples were obtained from those trees which received a blossom bud application of a rather strong lime-sulphur solution to which lead arsenate was added, followed by two applications of lead arsenate, and from trees which were treated with lead arsenate alone. The application of dormant strength limesulphur after the leaf buds had begun to open, but at a time when the flower buds were still thoroughly protected, increased the amount of fruit russeting in a way that does not seem to be readily explained. The author, as a result of his investigations, does not consider the applying of dormant sprays later than usually recommended for use against scale and similar insects as of advantage from the standpoint of scab prevention.

An account is given of winter injury to Baldwin apple trees set in dynamited holes, comparison being made with those planted in dug holes. The trees were planted in 1913 in a soil having a hardpan subsoil, and in 1915, out of 126 trees set in holes previously dynamited, 49 were either winterkilled or badly injured, while of 52 trees set in shovel-dug holes, only 4 suffered in a like manner. No attempt is made to draw general conclusions from these figures, but it is believed that the method of setting trees in dynamited holes is not adapted to soil conditions at the Maine Station.

Two apple-leaf troubles new to Maine are described, a chlorosis in which the leaves are variously spotted or mottled with irregular splotches of yellow, and a silver leaf which had been previously reported in Europe but had not been observed in Maine. The cause of the chlorosis has not been definitely determined, nor has the author been able to confirm the connection between silver leaf and the occurrence of Stereum purpureum. This fungus was not

observed on any of the trees, although it is known to follow winter injury to apple trees in Maine.

Some further observations are given relative to the ability of the apple-scab fungus to live over the winter on young twigs, confirming and extending those previously noted (E. S. R., 30, p. 542). Specimens were observed in 1914 and 1915 indicating that the disease was carried over in the young twigs, and in 1916 these observations were extended to include scab infections on pear limbs.

The treatment of peach leaf curl, C. GANDOLFI (Coltivatore, 61 (1915), No. 14, pp. 435-437; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 7, p. 1000).—Experiments carried out for several years in northern Italy showed complete freedom from peach leaf curl in case of trees which were covered with muslin nets, while trees left uncovered but sprayed with Bordeaux mixture late in November and again about the middle of February were attacked. A glass roof also gave freedom from leaf curl. The method of protection with muslin is said to assure a practically constant setting of the fruit.

The 1915 outbreak of downy mildew in France and Italy, J. Pastre (Prog. Agr. et Vit. (Ed. VEst-Centre, 37 (1916), No. 16, pp. 368-380; abs. in Rev. Sci. [Paris], 54 (1916), I, No. 10, p. 313).—A résumé is given of observations, opinions, and conclusions resulting from the investigations of the Central Society of Agriculture of Herault regarding the severe and extended outbreak of mildew in 1915, which copper sprays very frequently failed to check in the usual manner.

The date of treatment is regarded as extremely important. The time of greatest susceptibility to infection appears to be the blooming period. The violence of the 1915 outbreaks is thought to have been due to the multiplication of spores in 1914, lack of vigilance and proper treatment on account of the war, and abundant rains in May, 1915, with high temperatures, dews, and fogs late in May and early in June when the vines were in bloom, to which should be added, it is thought, a certain tolerance established for the copper sprays by the parasitic fungus. Attack by  $Glxosporium\ nervisequum$ , said to precede usually the mildew of grapes, is said to have been wanting in 1915. Exceptions are noted also as regards the behavior of varieties ordinarily immune or nearly so to mildew.

The various treatments tested in Italy and France are detailed in separate tables, according to their results as good or bad. The several treatments which have been recommended or are in use are discussed in some detail as regards their composition, preparation, and application.

Downy mildew, its manifestations and directions for its control, L. RAVAZ (*Prog. Agr. et Vit.* (*Ed. VEst-Centre*), 37 (1916), No. 15, pp. 341-347).—A summation is given of known facts regarding the times, conditions, and modes of attack and development of downy mildew, which has recently been severe on grapevines in parts of France, also regarding measures looking to its control.

Cupro-ferric sprays for downy mildew and chlorosis, A. Donadeu (*Prog. Agr. et Vit.* (*Ed. l'Est-Centre*), 37 (1916), No. 10, pp. 224, 225).—The author states that grapevines persistently showing chlorosis in a fertile but low and basin-shaped area recovered and continued free from mildew and chlorosis, healthy, and productive from 1912 to 1915 as a result of the adoption of a combined spraying liquid for the foliage. This spray was made up by adding to a previously prepared Burgundy mixture sufficient iron sulphate (previously dissolved in a little water) to give a strength of 0.1 per cent of this salt. The preparation should be acid and should be applied early but sparingly to avoid scorching.

Cupro-ferric sprays for downy mildew and chlorosis, A. Donadieu (Prog. Agr. et Vit. (Ed. VEst-Centre), 37 (1916), No. 12, pp. 271, 272).—Responding to inquiries regarding the treatment above mentioned, the author gives the formula employed. This requires 2,000 gm. copper sulphate and from 750 to 800 gm. sodium carbonate in 100 liters of water, with the addition, when the above has been properly made up, of 100 gm. iron sulphate.

Treatments for downy mildew and the preparation of copper sprays, L. Degrully (Prog. Agr. et Vit. (Ed. VEst-Centre), 37 (1916), No. 14, pp. 317–324).—Enlarging on the statement that the experience of 1915 showed that copper does not necessarily constitute an ideal remedy for mildew, at least under the usual forms and conditions recently found in actual practice, the author discusses the great influence of the time factor as related to outbreaks; the duration of the effectiveness of one spraying (in 1915 not over four to five days); the suitable preparation of sprays and the proper dosage thereof; the acid, alkaline, neutral, and casein preparations of Bordeaux and several other preparations. It is stated that in regions severely attacked in 1913 to 1915 only those grape growers saved their entire product who employed treatment without intermission throughout the whole of the danger period.

Mottle leaf of citrus trees in relation to soil conditions, L. J. BRIGGS, C. A. JENSEN, and J. W. McLane (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 19, pp. 721-740, pls. 3, figs. 4).—The authors report a study of the cause of mottle leaf of citrus trees which is characterized by the disappearance of the chlorophyll of parts of leaves. The principal conclusion of their investigation is that the mottling of orange trees in the areas studied is definitely correlated with a low humus content of the soil, the mottling diminishing as the humus content increases. It is claimed that approximately one-half of the mottling can be accounted for in this way and that the incorporation of organic matter with the soil in such a manner as to be readily accessible to the roots during its decomposition is a promising treatment for this trouble.

Fighting a fungus, Pythiacystis citrophthora, in the citrus orchards, H. S. FAWCETT (Univ. Cal. Jour. Agr., 3 (1916), No. 8, pp. 339-343, 356 figs. 3).—The fungus P. citrophthora, isolated and described by Smith in 1906 as the cause of brown rot of lemons (E. S. R., 19, p. 658) and shown by the present author in 1913 (E. S. R., 30, p. 51) to cause also a form of gummosis in the bark, is here discussed as to the conditions, modes, and consequences of its attack, and as to its control.

Bordeaux mixture as a spray is deemed practically preventive, as is also fresh Bordeaux paste in connection with surgery when the trunk is attacked, which usually occurs near the surface of the ground. Sour orange is very resistant and desirable to use for stocks. These should, however, be budded high and so planted as to keep the bud unions as far as possible from the surface of the ground.

A serious disease of cultivated perennials caused by Sclerotium rolfsii, G. L. Peltier (Illinois Sta. Circ. 187 (1916), pp. 4, fig. 1).—It is stated that during the summer of 1915 a large number of perennial ornamental plants were found dying from crown rot. An investigation of the disease showed that it was due to the fungus S. rolfsii. The disease is said to have made its first appearance in July and to have killed a large number of plants during the warm weather. It persisted until late in October, although with cooler weather the attack became less severe. Among the ornamentals attacked were several species of Campanula, Phlox, Dianthus, Eupatorium, etc. The outbreak of the disease is attributed to the extremely wet summer, and it is considered doubtful whether, under normal conditions, the disease will ever become serious in Illinois.

Two timber-destroying fungi, J. B. CLELAND and E. CHEEL (Agr. Gaz. N. S. Wules, 27 (1916), No. 3, pp. 201, 202, pls. 2).—Descriptions are given of fungi which cause tree rots of economic importance.

Pleurotus nidiformis, a variable species which has received different names, is a common phosphorescent toadstool found near the bases of Eucalyptus and other trees in each of the Australian States. Pholiota adiposa, a common and supposedly destructive parasite of timber in Europe, has been found at Mount Wilson in New South Wales and has been recorded also for Queensland.

Anomalies of growth in Pinus, C. von Tubeuf (Naturw. Ztschr. Forst u. Landw., 13 (1915), No. 11-12, pp. 550-555, figs. 3).—Descriptions are given of an anomalous shoot arrangement and bud formation and of a cone disease in P. sylvestris.

# ECONOMIC ZOOLOGY-ENTOMOLOGY.

Ground squirrel control, W. T. Shaw (Washington Sta. Popular Bul. 99 (1916), pp. 11, pls. 2, figs. 4).—The station has given attention to the habits and means of controlling three species of ground squirrels, the Columbian ground squirrel (Citellus columbianus), Townsend ground squirrel (C. townsendi), and Yakima ground squirrel (C. mollis yakimensis).

Careful life history studies have been made of the Columbian ground squirrel, and have shown that the squirrels come out of hibernation at Pullman, Wash., about February 20 and remain active until July. The burrowing and feeding habits of the animals indicate quite clearly that all remedies for controlling them may be applied with more success during the first nine weeks of their spring activity. The remedies which have given satisfactory results during this time include carbon bisulphid, trapping, and the use of poisoned grain. Detailed directions for applying these remedies are given.

Important foreign insect pests collected on imported nursery stock in 1915, E. R. Sasscer (*Jour. Econ. Ent.*, 9 (1916), No. 1, pp. 216-219).—This is a summary of the results of inspection work in 1915.

Inspection facilities in the District of Columbia, E. R. SASSCER (Jour. Econ. Ent., 9 (1916), No. 1, pp. 219-223, pls. 3).—A description of the inspection equipment.

Foreign pests recently established in New Jersey, H. B. Weiss (Jour. Econ. Ent., 9 (1916), No. 1, pp. 212-216).—A considerable number of insects which have been discovered during the past two years to have become established in varying numbers in different parts of New Jersey are here recorded. It is stated that practically all were introduced on imported nursery stock, and their presence is considered an indication of the impossibility of keeping out all foreign pests by a system of inspection.

On the Hawaiian work in introducing beneficial insects, L. O. HOWARD (Jour. Econ. Ent., 9 (1916), No. 1, pp. 172-179).—A review of the work carried on in the Hawaiian Islands.

Results of experiments on the use of cyanid of potassium as an insecticide, W. Wellhouse (Jour. Econ. Ent., 9 (1916), No. 1, pp. 169-171. pl. 1).—A report of preliminary experiments, conducted with the view of ascertaining the effect of cyanid of potassium on plant tissues and on scale insects and borers, begun in 1915. Severe injury was found to follow its insertion in the stems and trunks of plants and trees, and the insects were unaffected.

Proceedings of the Entomological Society of British Columbia (*Proc. Ent. Soc. Brit. Columbia*, n. ser., No. 5 (1915), pp. 79-98, pls. 4).—The papers here presented include the following: A Note on the Occurrence and Significance of Anophelinæ in British Columbia, by S. Hadwen (pp. 81, 82); Aphid Notes

from British Columbia, by H. F. Wilson (pp. 82-85); Notes on the Early Stages of *Calocampa cineritia*, by G. O. Day (pp. 86, 87); A Description of the Egg and Ovipositor of *Cuterebra fontinella*, the Cotton-tail Bot, by S. Hadwen (pp. 88-91); Notes on the Habits of Some Lepidoptera, by J. W. Cockle (pp. 91-94); Notes on the Early Stages of *Epirrita dilutata*, by G. O. Day (pp. 95, 96); and The Oyster Shell Scale, by T. Wilson (pp. 96, 97).

Some insect enemies of shade trees and ornamental shrubs, M. W. BLACK-MAN and W. O. Ellis (N. Y. State Col. Forestry, Syracuse Univ. [Pubs.], 16 (1916), No. 26. pp. 123, pl. 1, figs. 60).—A summarized account of six of the more important leaf-eating insects, eleven boring insects, and ten scale insects (pp. 11-112) is followed by an account of spraying and spraying apparatus.

Insects in their relation to the chestnut bark disease, F. C. CRAIGHEAD (Science, n. ser., 43 (1916), No. 1100, pp. 133-135).—This is a critical review of the bulletin by Studhalter and Ruggles, previously noted (E. S. R., 34, p. 853). It is pointed out that the beetle Leptostylus macula, which the above-mentioned authors state is the insect of most importance in the local dissemination of the disease, under normal conditions never frequents healthy trees, and that to disseminate this disease it would be necessary for the beetle to migrate from infested to healthy trees.

Controlling the coulee cricket, A. L. Melander (Washington Sta. Popular Bul. 101 (1916), pp. 3).—The means of combating this pest are briefly described. It is said to be easily possible to locate the restricted breeding areas and to destroy the young crickets:

A new species of Thripoctenus, L. T. WILLIAMS (Psyche, 23 (1916), No. 2, pp. 54-61, fig. 1).—Under the name Thripoctenus nubilipennis the author describes as new a form found to parasitize the larvæ of either one or both of two species of thrips, Megalothrips spinosus and Cryptothrips rectangularis, at Forest Hills, Mass.

The false cabbage aphis (Aphis pseudobrassicæ), J. J. Davis and A. F. Satterhwait (Indiana Sta. Bul. 185 (1916), pp. 915-939, figs. 7; pop. ed., pp. 4).—This plant louse, an account of which by Paddock of the Texas Station has been previously noted (E. S. R., 34, p. 452), is said to be distributed from Manitoba to Texas and from Massachusetts to California, apparently occurring in potential numbers wherever wild mustard grows, and to be destructively abundant where turnips or radishes are planted. It may also become a serious enemy of greenhouse crops.

The present bulletin is based upon life-history studies commenced in October, 1913, and carried on during 1914 at La Fayette, Ind., in cooperation with the Bureau of Entomology of the U. S. Department of Agriculture.

Technical descriptions are given of the five instars of the viviparous generation and of the winged viviparous female. Studies of its life history and habits reported in detail include tables which show the consecutive generations observed at La Fayette, Ind., from 1913 to 1915, and a figure showing the duration of generations. A comparison shows this plant louse to be more prolific than any other recorded species, thus indicating its great importance as an enemy of cruciferous plants.

Its natural enemies apparently do not appear in effective numbers until late in the fall after the plant lice have damaged the crop. Diaeretus rapw and Pachyneuron micans have been reared from it by the authors, and Aphidoletes sp. and a syrphid larva have been observed to be predacious on it. Empusa aphidis is also an important check in late fall.

Control measures consist in the use of a 40 per cent solution of nicotin at the rate of 1:1,200, with 4 lbs. of soap to each 50 gal. of water. In greenhouses

this treatment may be used, or fumigation with hydrocyanic acid gas, directions for the use of which are given.

The western wheat aphis (Brachycolus tritici), J. R. PARKER (Jour. Econ. Ent., 9 (1916), No. 1, pp. 182–187, pl. 1).—This aphidid, described by Gillette from Colorado in 1911, first attracted attention in a few localities in Fergus County, Mont., in 1910. In this year an investigation of the reports of injury led to the determination of the fact that it was causing serious injury to winter wheat. In one instance, a grower who had 700 acres of wheat estimated his loss at 5,000 bu., while 80 acres of wheat on another farm were so badly injured that no attempt was made to harvest it. Since 1910 the western wheat aphis has become increasingly abundant in Fergus County and has appeared in injurious numbers in several other counties.

This paper presents descriptions of the pest and discusses the character and extent of injury, seasonal history and habits, and control measures. Barley is said to be the only grain crop besides wheat thus far known to be injured by the wheat aphis. Blue joint grass (*Agropyron occidentale*) when growing in and around the edges of infested wheat fields is always heavily infested and is probably the native host plant.

Plant lice injurious to apple orchards.—I, Studies on control of newly hatched aphids, P. J. Parrott, H. E. Hodgkiss, and F. H. Lathrop (New York State Sta. Bul. 415 (1916), pp. 11–53, pls. 8, figs. 6).—The experiments and observations quoted in this bulletin were made chiefly at Geneva, but auxiliary experiments were carried on with more than 400 trees in 10 orchards in Niagara and Orleans counties. The work was chiefly concerned with control methods on newly hatched aphids. For this purpose lime-sulphur, nicotin solution, sodium sulphid mixed with soap, crude carbolic emulsion, and other insecticides were used. Observations were also made on the seasonal behavior of apple aphids and on the influence of these insects on the growth of apples. The species of plant lice under observation were Aphis sorbi, A. avenæ, and A. pomi.

The rosy aphis (A. sorbi) was chiefly responsible during 1915 for the dwarfing and deforming of apples. The effects of the other two species were not so clearly distinguished. The rosy aphis caused a retardation of increase in the transverse diameter of apples at first, but ultimately brought about a reduction of the axillary diameter of the fruit. Infested apples showed an average axillary diameter of 1.51 in. and transverse diameter of 1.71 in., as contrasted with 2.37 and 2.87 in., respectively, for the diameters of uninfested apples.

Satisfactory results in controlling the rosy aphis were obtained from the use of nicotin solution and soap, nicotin solution and lime-sulphur, and crude carbolic-acid emulsion. The first insecticide caused no injury to foliage, while slight injuries resulted from the use of the other two. The insecticides used in this experiment were equally efficacious against the other species of insects, but the multiplication of green aphis made repeated applications necessary to control this species. Evidence was obtained that the soap and nicotin solution brings about only a temporary protection. The value of the insecticide appeared to be enhanced by the addition of large amounts of lime.

Apple aphids and their control, F. H. Hall (New York State Sta. Bul. 415, popular ed. (1916), pp. 11, figs. 2).—A popular edition of the above.

Some grass-feeding mealy bugs, T. D. A. Cockerell (Jour. Econ. Ent., 9 (1916), No. 2, pp. 312, 313).—Pseudococcus timberlakei on salt marsh grass at Millbrae, Cal., and P. neomexicanus utahensis from Elymus at Salt Lake City, Utah, are described as new to science.

California green lacewing fly, V. L. WILDERMUTH (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 14, pp. 515-525, figs. 7).—A report of studies of

Chrysopa californica carried on during 1915 in southern Arizona, where it is of considerable importance, particularly as an enemy of aphids. The species is known to occur throughout the Pacific Coast States and in Texas, Arizona, New Mexico, Nevada, Utah, and southern California. In addition to plant lice it feeds upon mites, leaf hoppers, thrips, etc.

Oviposition requires from one to four days, during which time about 30 eggs are deposited. From 6 to 12 days were passed in the egg stage, 8 days being the average for 122 eggs observed. From 11 to 22 days are required for the development of larvæ, 16 days being the average, during the course of which there are two molts and from 74 to 160 full-grown aphids were eaten by each larva. The pupal stage was found to vary from 14 to 23 days in length, the average being  $16\frac{1}{8}$  days for March and  $20\frac{7}{11}$  days for November. The author's observations show that there are at least six generations annually in the Salt River Valley.

Though reported to be commonly attacked by parasites in California, examinations of abundant material failed to detect any in Arizona.

Larval characters and distribution of two species of Diatrea, T. E. HOLLOWAY (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 16, pp. 621-626, pl. 1, flg. 1).—The differences in the larval characters of Diatrea saccharalis crambidoides and D. zeacolella are pointed out and descriptions given of full-fed larvae of both the summer and winter forms of the two species.

The food plants and breeding habits of the two have been found to differ to some extent. D. saccharalis crambidoides feeds on sugar cane, corn, and Johnson and other grasses, practically all the larval period being spent within the stalks of the plants, except that the first instars feed about on the leaves. D. zeacolella, however, seems to have a preference for corn even when sugar cane is present and goes down in the taproots of corn, which D. saccharalis crambidoides does not do. The last mentioned form has been found to be limited to southern Florida, southern Louisiana, and the southern tip of Texas, indicating that it was brought to this country in shipments of sugar cane from the Tropics.

Notes on the life history of Ecpantheria eridanus, R. H. VAN ZWALENBURG (Insecutor Inscitiæ Menstruus, 4 (1916), No. 1-3, pp. 12-17).—This arctiid moth (E. eridanus, of which E. icasia is a synonym) is said to be fairly common throughout the island of Porto Rico and to have a wide variety of host plants. It has been taken on the orange, Erythrina micropteryx, Ipomæa sp., vanilla, banana, Cissus (?) sicyoides, and Panicum sp. At the experiment station the larvæ have done some damage by feeding on the blossom buds of vanilla. The synonymy of E. eridanus and E. icasia is said to have been substantiated by breeding both forms.

Technical descriptions of the adult and immature stages, including eight larval stages, are given. The eggs are deposited in large irregular clusters on the upper leaf surface, unfertilized females in captivity having each laid over 500 sterile eggs. From 6 to 8 days are required for the development of the egg, 24 to 62 days for the completion of the larval stages, and 15 to 20 days for the pupal stage. The ichneumon *Eremotylus angulatus* is said to parasitize the larvæ.

The army cutworm in Montana, R. A. Cooley and J. R. Parker (Montana Sta. Circ. 52 (1916), pp. 97-108, figs. 4).—Information previously noted (E. S. R., 33, p. 654) is supplemented by observations in 1915, when a state-wide outbreak of the army cutworm (Chorizagrotis agrestis) resulted in the destruction of at least 100,000 acres of grain, principally winter wheat. Notes by A. Atkinson on crops to plant where winter wheat has been destroyed are appended.

Notes on the relation of insects to the spread of the wilt disease, H. W. ALLEN (Jour. Econ. Ent., 9 (1916), No. 1, pp. 233-235).—Very little is known

as to how the causative agent of wilt disease of the gipsy moth is spread. It apparently is not essentially a wind-borne disease. Certain insects occurring abundantly in association with the disease frequent the foliage of trees, and were found to carry polyhedra after contact with the wilt, which indicates that they may assist in spreading the infection.

Observations of the pine spinner in the greater coniferous forests in Neustadt-an-der-Warthe, 1913-14, Seitner (Centil. Gesam. Forstw., 41 (1915), No. 5-6, pp. 161-173, figs. 5).—A report of observations of the biology. parasitism, etc., of Gastropacha pini during the course of an outbreak of the pest in 1913-14.

Four European Diptera established in North America, F. K_{NAB} (Insecutor Inscitiæ Menstruus, 4 (1916), No. 1-3, pp. 1-4).—The author's study tends to show that Pegomya vicina of Lintner is a synonym of P. hyoscyami. This pest appears to be widely distributed in North America, probably occurring wherever the sugar beet is cultivated, since it is known to range as far south as Washington, D. C., in the East and into southern California in the West.

Hydrotæa meteorica is said to be abundant and troublesome to cattle in Montana, and is also known to occur in Colorado and North Dakota. The borborid Leptocera sylvatica is recorded from Arlington, Va.

The hippoboscid *Lynchia maura*, a common parasite of the domestic pigeon in the Mediterranean region, is said to have been collected from this host at Key West, Fla. It is also recorded as occurring in Iowa, Georgia, Cuba, Brazil, and Venezuela, and has recently made its appearance and become very common on pigeons in Hawaii.

Tanypezidæ in the United States, F. Knab and R. C. Shannon (Insecutor Inscitiæ Menstruus, 4 (1916), No. 1-3, pp. 33-36).

A revision of the nomenclature of Indian Anophelini, S. R. CHRISTOPHERS (Indian Jour. Med. Research, 3 (1916), No. 3, pp. 454-488).—This paper, relating to the malarial mosquitoes, deals with some 38 species. It includes a table for their separation and a list of references to systematic work on the species and to the transmission of malaria by particular Indian species.

An Indian tree-hole breeding Anopheles, A. barianensis (Coelodiazesis plumbeus), S. R. Christophers (Indian Jour. Med. Research, 3 (1916), No. 3, pp. 489-496, pl. 1).—The author reports observations of the breeding habits of this species, previously unknown, and gives descriptions of the immature stages.

Anopheles crucians, their infectibility with the parasites of tertian malaria, M. B. MITZMAIN (Pub. Health Rpts. [U. S.], 31 (1916), No. 12, pp. 764, 765).—"In the course of a series of infectivity experiments with A. punctipennis, conducted in New Orleans, 19 specimens of A. crucians were fed simultaneously, February 6 and 7, 1916, on the blood of an individual suffering from tertian malarial fever. Examination of the blood of this case showed large numbers of asexual parasites and but few mature gametocytes. . . The 38 specimens of A. punctipennis used in parallel feedings from the same case serve as a control series, 11 of these becoming infected from the sixth to the sixteenth day after biting; in 6 of these the salivary glands were extensively invaded with sporozoites. Two specimens of A. quadrimaculatus used under the same conditions as the foregoing remained negative throughout the course of the experiment."

An investigation of the supposed immunity of some varieties of wheat to the attack of Hessian fly, L. HASEMAN (Jour. Econ. Ent., 9 (1916), No. 2, pp. 291-294).—The author concludes from the data presented that some varieties of wheat are more severely attacked by the fly than others.

Summary of facts about the introduction of Pleurotropis epigonus, W. R. McConnell (Jour. Econ. Ent., 9 (1916), No. 1, pp. 145-147).—This article records the rearing of this parasite of the Hessian fly, first introduced from England in 1891, at Hagerstown, Md., and at several localities in Pennsylvania.

Parasitism among the larvæ of the Mediterranean fruit fly (Ceratitis capitata) in Hawaii during 1915, E. A. BACK and C. E. PEMBERTON (Jour. Econ. Ent., 9 (1916), No. 2, pp. 306-311) — The authors present tables to show the percentage of parasitism among C. capitata larvæ developing in coffee cherries (Coffea arabica) in the Kona District, in kamani nuts (Terminalia catappa) in Honolulu, and in various host fruits grown in Honolulu. The data for 1914-15 show that four introduced parasites, Opius humilis, Diachasma tryoni, D. fullacayi, and Tetrastichus giffardi, have established themselves and are already promising much as a factor in the control of the fruit fly.

Further notes on Prospaltella berlesei, L. O. Howard (Jour. Econ. Ent., 9 (1916), No. 1, pp. 179-181).—A further review of the beneficial work of this parasite in Italy (E. S. R., 34, p. 456).

Designations of muscoid genotypes, with new genera and species, C. H. T. Townsend (Insecutor Inscitiæ Menstruus, 4 (1916), No. 1-3, pp. 4-12).

Elucidations of New England Muscoidea, C. H. T. Townsend (Insecutor Inscitive Menstruus, 4 (1916), No. 1-3, pp. 17-33).

The life history of Hæmatobia sanguisugens, J. L. MITTER (Indian Jour. Med. Research, 3 (1916), No. 3, pp. 530-537, pl. 1).—This reports studies of the biology of this Indian species of bloodsucking muscid.

[The hickory bark beetle and the two-lined chestnut borer] (U. S. Dept. Agr., Bur. Ent., [Work of the Insects That Are Killing the Hickories and Oaks], 1916, pp. 4, figs. 2).—This leaflet calls attention to the destruction of hickory trees being caused by the hickory bark beetle and of oak trees by the two-lined chestnut borer on Long Island and gives remedies therefor.

A progress report on white grub investigations, J. J. Davis (Jour. Econ. Ent., 9 (1916), No. 2, pp. 261-281, pls. 3).—This report is based upon investigations of Lachnosterna commenced at La Fayette, Ind., in 1911. Eighteen species of white grubs are said to have been reared from egg to adult and adults of nine more will have been reared from eggs by another year. The present paper gives a brief summary of life history studies, comparison with related genera, field observations, natural enemies, and methods of control.

Lachnosterna records in Wisconsin, J. G. Sanders and S. B. Fracker (Jour. Econ. Ent., 9 (1916), No. 2, pp. 253-261, figs. 3).—Trap light collections of Lachnosterna at five stations in as many counties in the southern third of the State are reported upon. Seventeen of 19 species known to occur in Wisconsin were taken in the traps.

A study of the life history of the maize billbug, W. P. HAYES (Jour. Econ. Ent., 9 (1916), No. 1, pp. 120-130, pls. 3, fig. 1).—A report of studies of Sphenophorus maidis made in southern Kansas during the seasons 1914 and 1915.

The European species of Diprion (Lophyrus), E. Enslin (Naturw. Ztschr. Forst u. Landw., 14 (1916), No. 1, pp. 1-20, pl. 1).—A synopsis of the European forms of this important genus of sawflies.

Further notes on Diprion simile, W. E. BEITTON (Jour. Econ. Ent., 9 (1916), No. 2, pp. 281, 282).—This paper is supplementary to the account previously noted (E. S. R., 35, p. 54).

New Encyrtidæ from North America, A. A. GIBAULT (Psyche, 23 (1916), No. 2, pp. 41-50).—The new forms of economic importance include Signiphora thoreauini from Aspidiotus hederæ, at Santa Barbara, Cal.; Neosigniphora

elongata from a coccid on Muehlenbergia, at Elk Point, S. Dak.; Aneristus oculatipennis, reared from the black scale, at Catacaos, Peru; Formicencyrtus thoreauini (n. g.) from Coccus confusus, at Mesilla Park, N. Mex.; Zaommoëncyrtus submicans (n. g.) from Nyctobates pennsylvanica, at Shiremantown, Pa.; Ceraptroceroideus cinctipes (n. g.) from Aspidiotus helianthi on Eugerion canadense, at Wellington, Kans.; Berecyntus bakeri gemma from Euxoa larva, at Queensboro, Ont., and also from larva of Hadena devastatrix, at Ottawa, Canada; and B. bakeri arizonensis from Choraxagrotis sp., at Phoenix, Ariz. The author also records the rearing of S. flavopalliata occidentalis from Chrysomphalus aurantii citrinus at Avondale, Cal.

The Argentine ant: Distribution and control in the United States, E. R. BARBER (U. S. Dept. Agr. Bul. 377 (1916), pp. 23. fig. 5).—This bulletin includes the results of studies carried on in continuation of those by Newell and Barber, previously noted (E. S. R., 29, p. 563).

The pest has continued to spread and is now known to occur in nine southern States, the many infestations covering a total area of considerably more than a thousand square miles. At the time of writing it was known to occur from Houston, Tex., on the west to Wilmington, N. C., on the east, and from Nashville, Tenn., to the mouth of the Mississippi River. Among other cities known to be infested are Shreveport, La., Texarkana, Ark., Memphis, Tenn., Augusta and Atlanta, Ga., and Charleston, S. C. This wide distribution appears to have taken place with commodities shipped by steamboats and railroads.

The greater part of the bulletin deals with repression, particularly with ant poisons, of which the only effective ones for permanent control are poisoned sirups. Experiments have led to the recommendation of an improved formula said to be superior to any yet tested on account of its stability at high temperatures, freedom from crystallization, and continued attractiveness. This sirup, proposed by W. E. Cross, is prepared as follows: Granulated sugar 15 lbs., water 7 pints, tartaric acid (crystallized) ½ oz., boil for 30 minutes, allow to cool. Dissolve sodium arsenite (C. P.) ¾ oz. in 1 pint of hot water and cool. Add the poison solution to sirup, stir well, add 1.5 lbs. honey, and mix thoroughly.

A new method of subterranean fumigation, J. S. Houer (Jour. Econ. Ent., 9 (1916), No. 2, pp. 285-287).—The author reports preliminary experiments conducted at the Cuban agricultural experiment station with the fungus growing ant Atta insularis. The principle of the method of control consists in forcing vaporized carbon bisulphid into the ant hills.

Some difficulties in gross diagnosis of the infectious brood diseases of bees, A. H. McCray (Jour. Econ. Ent., 9 (1916), No. 1, pp. 192-196).—This is a discussion of some of the difficulties which have been encountered in the examination of over 4,500 different specimens of bee comb and brood, representing every section of the United States.

## FOODS-HUMAN NUTRITION.

The iodin content of foods, E. B. Forbes, F. M. Beegle, et al. (Ohio Sta. Bul. 299 (1916), pp. 487-546).—This bulletin presents data regarding the iodin content of a large number of samples of different foods. The investigation was undertaken on account of the rôle of iodin in the function of the thyroid gland and the possible significance of the iodin content of food in goiter.

Iodin determinations were made on a large number of common foods purchased in the market, and also on samples of the same kinds of food products grown under various conditions as to soil, climate, artificial fertilization, and geographical location. A wide range of both animal and plant products was in-

cluded in the study. The method employed was found to be accurate to 0.000003 gm. of iodin. The results of the experiments are presented in three tables as follows: An alphabetical list of the foods, showing the number of samples analyzed, the number containing iodin, and the maximum iodin content; a grouping of the foods according to their general class or characteristic; and a grouping of the foods according to geographical location of the source of the samples.

The following groups of foods are arranged in the order of increasing abundance of iodin, the first mentioned being that in which it is most rarely found: Nuts; spices, condiments, and stimulants; fruits; cereals; hays, silage, and forage crops; garden vegetables and root crops; leguminous seeds; animal products; manufactured foods and milling and manufactory by-products; and seaweeds. It was usually found in exceedingly small quantities, is by no means a constant constituent of foods, and is deemed, in most cases at least, strictly an accidental constituent.

Traces of iodin were found in butter, in eggs, and in several kinds of meat and fish, but none was found in 18 samples of cow's milk. Among the garden vegetables and root crops traces of iodin were found in beets, cucumbers, celery, onions, potatoes, and spinach.

"Of the hays, silage, and forage crops about 1 sample in 4 contained iodin. Among leguminous seeds iodin was found in 11 samples out of 32; more commonly among beans, peas, and cowpeas than among soy beans.

"The manufactured foods and milling and manufactory by-products contained iodin in 13 samples out of 25; of those containing iodin 10 were made from cereals. The offal parts of the grains are richer in iodin than are the more starchy parts.

"Agar agar and Irish moss (used in making blanc mange) were richer in iodin than any other products examined."

No iodin was found in 7 kinds of nuts examined and none in 16 samples of table salt.

"The more important sources of iodin in the human dietary . . . [aside from Irish moss] are the garden vegetables, though some is also found in the cereal foods, and in several foods of animal origin, mostly of the sorts less commonly used. Among the foods used by live stock the more important sources of iodin are the hay, silage, and forage crops, and also the milling and manufactory by-products, comparatively little being found in the natural grain foods."

While iodin was found to be more commonly present in foods from some regions than from others, no general geographical distribution of iodin in foods was discovered, and the iodin content of samples of the same food products from the same field often varied widely. "None of the ordinary methods of fertilization, or other details of management of the soil have been found, in any regular way, to affect the iodin content of field crops."

No relationship between the iodin content of foods and the prevalence of goiter was discovered.

An earlier report of this investigation has been noted (E. S. R., 35, p. 555).

The iodin content of foods, E. B. Forbes, F. M. Beegle, et al. (Jour. Med. Research, 34 (1916), No. 3, pp. 445-458).—The bulk of the material in this article is noted above.

Digestibility of very young veal, C. F. LANGWORTHY and A. D. Holmes (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 16, pp. 577-588).—This series of experiments was undertaken to determine the completeness of digestion of very young or "bob" veal by human subjects.

Preliminary tests were made in which the young veal was prepared by different methods and eaten by a number of individuals of varied ages and activities. In these cases no physiological disturbances resulted from the ingestion of the veal.

A series of digestion experiments was conducted with five normal young men in good health. The veal used in these experiments was obtained from calves not over five days' old and was eaten with a basal ration of fruit, bread and butter, and tea or coffee with sugar. The experimental periods were of three days or nine meals each. An average of 237 gm. of veal, which furnished 78 gm. of protein or approximately 75 per cent of the total protein in the diet, was eaten daily. The average value for seven experiments of the digestibility of the total protein in the diet was 92.9 per cent and of the protein of the veal 92.7 per cent. No physiological disturbances were experienced by the subjects, who reported that with the exception of one or two colds they were in normal physical condition throughout the investigation.

For comparison, a study was also made of the digestibility of market veal. Veal from animals at least four weeks old was purchased in the open market and fed with the same basal ration to the same subjects. In these experiments the digestibility of the protein of the total diet was found to be 92.9 per cent and the protein of the market veal alone was estimated at 92.8 per cent.

The results of these experiments indicate that the digestibility of the protein of bob veal is the same as that of market veal, or approximately 93 per cent.

The authors conclude that bob veal can be prepared for the table in palatable ways and is not unwholesome when eaten in quantity, since, during the digestion experiments, the average weight of protein furnished by the veal exceeded that generally furnished by meat in the ordinary diet. "The experiments here reported also indicate that the general opinion that young veal is a common cause of digestive disturbance or fails to digest as thoroughly as similar foods is not justified."

Digestibility of hard palates of cattle, C. F. Langworthy and A. D. Holmes (U.S.Dept.Agr., Jour.Agr.Research, 6 (1916), No. 17, pp. 641-648).— The hard palates, taken from the roof of the mouth of beef animals, consist chiefly of connective tissue (about 60 per cent) and erectile fibers (about 20 per cent) and contain very little muscular tissue, such as is characteristic of meats in general. Analysis showed the composition of the fresh material to consist of water, 71 per cent; protein ( $N \times 6.25$ ), 22.2 per cent (or protein by difference, 16.6 per cent); fat, 11.8 per cent; and ash, 0.6 per cent.

The high protein content suggested the possibility of the use of hard palates as food and their digestibility was studied by feeding them for a three-day period, with a basal ration of potatoes, crackers, butter, and tea or coffee with sugar, to four healthy young men as subjects. The cooked and finely ground hard palates were made up into a meat loaf which furnished 82 per cent of the total protein consumed. The digestibility of the protein of the meat loaf alone, which closely approximated that for the protein of the hard palates, was found to be 86.8 per cent.

The authors conclude from the results of this investigation that "it would seem that the protein of hard palates which have been thoroughly cooked is somewhat less thoroughly assimilated than that of the common cuts of meat."

"In view of the fact that over 130 gm. of protein, largely supplied by the meat loaf, and over 3,200 calories of energy were consumed daily, it is apparent that the ration was eaten with relish."

Artificial purification of oysters.—A report of experiments upon the purification of polluted oysters by placing them in water to which calcium hypochlorite has been added, W. F. Wells (Pub. Health Rpts. [U. S.], 31

(1916), No. 28, pp. 1848-1852).—An extended series of experiments carried out by the author indicates that "oysters which have lain in polluted water can be artificially purified to such a degree as to pass a most rigid standard by exposure for a short period in water containing calcium hypochlorite." The experiments appear also to demonstrate the feasibility of such a process.

The rapidity with which alcohol and some sugars may serve as nutrient, H. L. Higgins (Amer. Jour. Physiol., 41 (1916), No. 2, pp. 258-265, fig. 1).—
To determine how soon after its ingestion alcohol is burned in the body, determinations were made of the respiratory quotient for periods of from three to five minutes in length during the 15-minute interval following the ingestion of 30 cc. of absolute alcohol, taken in admixture with cold cereal coffee. In a similar way was studied the effect of the ingestion of the more common sugars, glucose, levulose, sucrose, lactose, and maltose. The following conclusions are drawn from these experiments:

"Alcohol begins to be burned in appreciable quantity in from 5 to 11 minutes after taking; with some subjects the combustion began more quickly than with others. Sucrose, lactose, and levulose begin to be burned quite as soon as alcohol, if not sooner. Glucose and maltose are not utilized as food as soon as the other sugars or alcohol, approximately 20 to 30 minutes elapsing before their combustion plays an important part in the metabolism. There is a distinct difference between the metabolism in men of glucose and levulose and galactose, as shown by a study of the gaseous exchange, especially the respiratory quotients."

Vanilla extract, J. R. Dean and J. O. Schlotterbeck (Jour. Indus. and Engin. Chem., 8 (1916), Nos. 7, pp. 607-614, figs. 2; 8, pp. 703-709).—Among the factors studied as influencing the quality of vanilla extract were the composition of the beans; the relative values of grinding or chopping; methods of drying; the moisture content of the beans; the effects of varying amounts of alcohol in the extract; the use of alkali; the addition of sugar, sand, and glycerin; the effect of grade and length of beans; the solvent action of vanilla extract on certain metals; the aging of the extract; and methods of manufacture. The opinions of different manufacturers on some important questions relative to vanilla extract were obtained by submitting to them a list of questions, which are given together with a composite of the answers. The following conclusions are drawn:

"Vanilla beans are improved on aging where the aging is conducted under proper conditions. Vanilla beans should be chopped and not ground.

"Vanilla beans can be dried without material loss of flavor if the drying is carefully carried out at room temperature (60 to 70° F.). Extracts made from dried beans have higher color and lead number values than those made from the same but undried beans. Where the beans are not dried the menstruum should be regulated to suit the moisture present in the beans.

"The physical constants are not greatly affected by the various amounts of alcohol in the menstruum as long as the amount of alcohol is sufficient to produce a clear extract. The color values are slightly increased and the lead number values are slightly decreased by an increase of alcohol up to a maximum of about 65 per cent. The flavor of an extract prepared with 60 per cent alcohol is superior to that made with 50 per cent alcohol.

"The resins of vanilla beans are of no value as flavoring agents, but are of value as fixatives for the flavoring compounds present and as coloring matter for the extract.

"Alkaline menstrua produce extracts that are higher in color and lead number values, but the alkali impairs the natural flavor of the beans.

"Short maceration and percolation will not produce the maximum extract. The hot process produces an inferior extract, one that is lacking in delicate aroma. The most desirable extract is produced only by long maceration at room temperature as in the circulatory displacement method.

"Sugar does not increase the color of the extract and should be added to the percolate. Glycerin tends to increase the color and should be added to the menstruum before percolation or maceration.

"Vanilla extract should not be left in contact with any metal that is not completely covered with tin.

"Vanilla extract is decidedly improved by aging. The period of the aging should be at least one year and should be carried out at room temperature (60 to 70° F.) and in unpainted, porous, wooden barrels."

A bibliography is appended.

[Food and drug inspection], E. F. LADD and ALMA K. JOHNSON (North Dakota Sta. Spec. Bul., 4 (1916), No. 6, pp. 132-163).—In addition to giving data regarding a number of samples of foods and drugs inspected, this bulletin contains an article by Mae A. Englehorn on the Drug Plants of North Dakota, abstracted on page 730, and an article by R. E. Remington on the use of starch in canned corn.

Portion of acts and documents relative to public hygiene.—The work of the Superior Council of Public Hygiene of France (Rec. Actes Off. et Doc. Hyg. Pub., Trav. Cons. Sup. Hyg. Pub. France, 42 (1912), pp. 889, figs. 5).—This publication presents in detail the results of the inspection of foods, drugs, and beverages, and contains information regarding the handling and sale of food products, the hygiene of containers for different kinds of foods, and the preservation and adulteration of foods.

Comparative statistics on foodstuffs and fuel for three years (Olympia, Wash.: State, 1916, pp. 3).—The statistics given were based on prices prevailing in April of the years 1914–1916, inclusive, and were compiled by the state bureau of labor in connection with a study of the annual cost of living for a family of five persons.

Food for the family, A. Grace Johnson (Oreg. Agr. Col. Ext. Serv. Bul. 3 (1916), No. 10, pp. 13).—A summary of information regarding the functions and choice of foods, meal planning, etc.

Kitchen organization and administration, C. S. PITCHER (Columbus, Ohio: Bd. Admin., [1916], pp. 62 pls. 4).—This paper, read at a meeting of the American Association of Officials of Charity and Correction, deals with the construction of kitchens, the equipment of kitchen and dining rooms, employees, and methods for the control of kitchen and table waste. The data given include standard basic dietary tables.

The problems of physiological and pathological chemistry of metabolism, O. Von Fürth, trans. by A. J. Smith (Philadelphia and London: J. B. Lippincott Co., 1916, pp. XV+667).—This is an English translation of one volume of the original German edition. The material presented is based upon a series of 25 lectures, the purpose of which is to present the subject of normal and pathological metabolic chemistry as a broad and connected whole. In addition to an extended discussion of the digestion and metabolism of proteins, fats, and carbohydrates, chapters are devoted to the nutritional requirements of the body, energy and gaseous metabolism, tissue respiration, and fever.

The influence of the nature of the diet on the retention of protein, N. UMEDA (Biochem. Jour., 10 (1916), No. 2, pp. 245-253).—Experiments are reported in which a laboratory animal (dog) was given diets containing the same amount of protein and of the same fuel value, but varying greatly in their content of fat and carbohydrate. The following combinations were used:

Carbohydrate-rich, fat-poor diet; intermediate diet; and fat-rich, carbohydrate-poor diet. Each diet was preceded and followed by a period of several days, during which time a standard diet was given. The following conclusions are drawn:

"Nitrogen in the form of protein added to a carbohydrate diet is retained in greater amount than when added to a fat diet of equal caloric value. Nitrogen given in the form of caseinogen is more completely retained than when given in the form of gelatin. The addition of meat extract to gelatin does not increase the amount of nitrogen retained."

The protein metabolism of an infant, F. B. TALBOT and J. L. GAMBLE (Amer. Jour. Diseases Children, 12 (1916), No. 4, pp. 333-344, figs. 1).—This paper reports observations upon an infant receiving a diet in which the protein was increased in each successive period. It was found that the metabolism went on in a normal manner in spite of the increase of protein.

"The endogenous metabolism of uric acid, creatinin, and ethereal sulphates was maintained on a very constant level, while the exogenous metabolism, namely, urea, creatin, inorganic sulphates, and the metabolism of phosphates, chlorids, and undetermined nitrogen increased with the protein in the food. The fat and carbohydrate absorption was within normal limits, although the fat utilization . . . [in two periods] was almost outside normal limits. The retention of nitrogen suddenly dropped in the last period, even though there was a greater intake and absorption of nitrogen. This loss was found in the stools, in which casein curds were found in large numbers. The ammonia in the stools increased with the increasing protein intake, and may be considered an index of intestinal putrefaction."

Effect of autolysis upon muscle creatin, R. Hoagland and C. N. McBryde (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 14, pp. 535-547).—The data obtained in these experiments are reported as a contribution to the knowledge of the source and method of production of creatinin in the animal body.

In one series of experiments, under aseptic conditions, pieces of muscular tissue were cut from the hind quarter of a steer, sealed in sterile dishes, and allowed to undergo aseptic autolysis at 37° C. for periods ranging from 7 to 100 days, at the end of which the percentages of free and total creatinin were determined. Only such samples as were found on bacteriological examination to be sterile were used. In another series antiseptic methods were employed, chiefly as a check and for comparison with the aseptic method. Pieces of muscular tissue were finely ground with sand and placed in flasks with salt solution, chloroform and toluol being added to prevent bacterial growth. These were kept at 37° for periods ranging from 2 to 84 days and the percentages of total and free creatinin determined. In both series of experiments analyses were made of samples of the fresh muscular tissue for comparison.

The results of these experiments show that muscular tissue has the power, in a marked degree, to convert creatin into creatinin and has the ability, in an appreciable degree, both to produce and destroy creatinin. It was also found that during the course of autolysis an equilibrium is finally established between creatin and creatinin. This, in the opinion of the authors, denotes that "in autolyzing muscular tissue the rate of reaction is very greatly accelerated, but that the total extent of the change is the same in either case. The more rapid change of creatin into creatinin in the autolyzing tissue may safely be assumed to be due, in large part, at least, to enzym action. This conforms to our idea as to the catalytic nature of enzyms. The gradually reduced rate of change of creatin to creatinin during autolysis is in conformity with the law of mass action."

In the animal body the change of creatin to creatinin takes place at its maximum velocity, since the creatinin is rapidly removed. The fact that muscular tissue has the power to convert creatin into creatinin is important evidence in support of the theory that muscle creatin is the source of urinary creatinin with a creatin- and creatinin-free diet, and also that the transformation of creatin into creatinin takes place in part at least in the muscular tissue.

The influence of diet on the development and health of the teeth, J. I. Duband (Jour. Amer. Med. Assoc., 67 (1916), No. 8, pp. 564, 565).—Studies of other investigators reviewed here indicate that the teeth of children fed during six months of the first year on sweetened condensed milk showed a higher percentage of caries (about 72 per cent) than those of children fed upon breast milk or modified cows' milk (about 42 per cent). The author states that "a poorly balanced diet, high in carbohydrate and low in fat, protein, and mineral constituents, fed during the period in which the teeth were developing and calcifying in the jaws, seems to have rendered them doubly susceptible to decay after they erupted."

Emphasis is also laid upon the advantage of tough and hard foods, which develop the muscles of mastication and enlarge and strengthen the jaws, and upon the cleaning effect of such foods as meat, fresh vegetables, acid fruits, and fibrous foods. Also, the ptyalin content and alkalinity of the saliva secreted vary with the flavor, acidity, or hardness of foods. Acid fruits, producing a highly alkaline saliva with a high ptyalin content, are recommended as valuable foods with which to finish a meal.

Dietary deficiency as the etiological factor in pellagra, E. B. Vedder (Arch. Int. Med., 18 (1916), No. 2, pp. 187-172).—In this paper the author considers the analogies which exist between pellagra and the two deficiency diseases beri-beri and scurvy, and also the question of whether the evidence pointing toward infection can be explained on the deficiency hypothesis. An extended study is reported of the diets of a large number of pellagrins, in order to determine whether or not a deficiency could be demonstrated in these diets. The author considers also a number of changes which have occurred during the past 10 years in the South which may account for the increase in pellagra. The following conclusions are drawn from the investigation:

"There is a certain similarity between pellagra and other known deficiency diseases, namely, beri-beri and scurvy. Much of the evidence that has been presented as a proof of the infectious nature of pellagra can be reasonably explained in accordance with a deficiency hypothesis.

"A deficiency is demonstrable in the diets of most pellagrins. This deficiency appears to . . . [the author] to result from the too exclusive use of wheat flour, in association with corn meal, salt meats, and canned goods, foods that are known to be deficient in vitamins.

"Changes in the diet of the people of the South have occurred during the past 10 or 15 years. Since . . . [all the changes that have occurred are not known and the importance of the known changes can not be judged accurately], it is unscientific to assume that the recent increase in pellagra can not be due to such changes.

"The hypothesis that pellagra is caused by a deficiency is very plausible and must be taken into consideration in subsequent studies of this disease."

Some metabolic effects of bathing in the Great Salt Lake, II, Helen I. and H. A. Mattill (Amer. Jour. Physiol. 41 (1916). No. 2, pp. 143-152).—This investigation was made to determine whether the findings in an earlier study (E. S. R., 33, p. 367) were significant and constant.

"Two subjects were maintained on a uniform diet for twelve days. A bathing period of four days followed a fore period of five days, with a three-day

final period. The urine was analyzed in 24-hour periods on all of the days and in short periods (three to four hours) on three bathing and on three nonbathing days.

"In agreement with former results the progress of the bathing period was attended by increased nitrogen and salt excretion, which, in this case, however, persisted through the final period. The three-hour period during and immediately following the bath showed a considerable increase (15 to 50 per cent) in nitrogen and salt excretion as compared with the same period on days when no bath was taken, indicating that the bath had an immediate influence as well as a prolonged effect.

"A constant and uniform parallelism between nitrogen and chlorid variations, noted also in earlier work, is not understood. Decreased perspiration through the cooling of the skin by the bath can account in only small measure for the greater salt and nitrogen excretion in the urine following the bath."

The pathological and therapeutic bearings of the elimination of body heat, J. B. Nichols (Med. Rec. [N. Y.], 90 (1916), No. 12, pp. 492-495).—In this article a number of factors are considered which influence the rate of elimination of body heat.

A respiration calorimeter, partly automatic, for the study of metabolic activity of small magnitude, C. F. Langworthy and R. D. Milner (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 18, pp. 703-720, pls. 4).—This article describes in detail the construction and operation of a small respiration calorimeter, which has been briefly noted in earlier publications (E. S. R., 27, p. 568; 29, p. 462).

The results are reported of electric and alcohol check experiments, which show that the heat and the products of respiration generated in the chamber may be determined with a high degree of accuracy in this respiration calorimeter.

### ANIMAL PRODUCTION.

Rape as material for silage, A. R. Lamb and J. M. Evvard (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 14, pp. 527-533).—Experimental silage was prepared at the Iowa Experiment Station from rape alone and from mixtures of rape with various other materials, such as alfalfa, red clover, sweet clover, potato tubers, timothy, Sudan grass, sorghum cane, and blue grass, with the purpose of determining the most satisfactory combination.

The rape used was quite mature but still succulent. The rape leaves were cut off at the main stalk, and the entire plant was cut 3 in. from the ground. The alfalfa was cut just before blooming. The corn, Sudan grass, and sorghum cane used were mature. The other plant materials were cut just before maturity. All the forage was cut by a silage cutter into half-inch lengths. The material was tightly packed into glass jars of about 1-gal. capacity. The jars were closed with metal caps, which were not too tight to prevent the escape of excess gases.

The jars were opened four months after filling and the condition, appearance, odor, and taste of the silage noted. With very few exceptions it was in a perfect state of preservation, of excellent texture and color, with a pleasant, somewhat aromatic odor, and generally of an agreeable taste, though quite sour. It was succulent without being too moist.

In order to ascertain its palatability to swine, a representative number of the various mixtures and some of the pure rape silage were fed to three lots of pigs. At first the animals, which were on a ration consisting mainly of corn and tankage, tasted the silage rather hesitatingly and seemed surprised by the sourness, but kept at it until they had eaten it all, appearing to enjoy its succulency. On a second trial, three days later, the same animals ate it with great relish. Only one sample of those tried, a rape-molasses mixture, was refused by the animals.

It is thought that those mixtures containing fibrous material, such as sorghum cane, Sudan grass, timothy, and the corn plant, would be useful for cattle, but would not be as good feed for swine as pure rape silage, or the alfalfa, red clover, potato, or corn-grain mixtures. The mixtures of rape with legumes are deemed perhaps best from the standpoint of feeding as well as that of the quality of the silage. The rape improves the mixture, in that it supplies the necessary fermentable carbohydrates, which apparently are deficient in amount in the legume.

Chemical examination of the samples showed the acidity and alcohol content to be comparable in most cases to that of corn silage.

A contribution to the bacteriology of silage, J. M. Sherman (Jour. Bact., 1 (1916), No. 4, pp. 445-452).—The data presented in this paper suggest the probable importance of a group of acid-tolerant, acid-producing bacilli in the curing of corn silage. The organism concerned, while closely related to the Bacillus bulgaricus group of milk and the B. acidophilus group of the intestines, appears to differ somewhat from the typical members of these groups, notably by its comparatively abundant growth on ordinary laboratory media. The microscopic examination of silage juice demonstrates the presence of immense numbers of bacterial cells (always over one billion per cubic centimeter), most of which are bacilli which resemble morphologically the high acid-producing bacilli described. The aciduric bacilli of silage are constantly found in quite large numbers on corn fodder, so that silage made from corn is always amply seeded with these organisms.

Fish meal: Its use as a stock and poultry food, F. C. Weber (U. S. Dept. Agr. Bul. 378 (1916), pp. 21).—The author notes the earlier use of fish meal as a feeding stuff in the United States and gives rather full abstracts of the more important literature pertaining to its use in this country and in other countries.

With proper attention to sanitary considerations in the processes, it is said that the undried fish residues may be made into fish meal for feeding purposes. The meal containing less than 10 per cent moisture will keep a very long time without decomposition.

During the season of 1914 a quantity of fish meal was made in the course of experiments upon the utilization as a stock food of the waste in the sardine industry on the coast of Maine. With the equipment used a yield of from 27 to 33 per cent of meal was obtained from the fish residue, and from raw material containing from 12 to 17 per cent of oil, over one-half the oil was removed by pressing. The oil obtained was bright, clear, and of a very high quality. After being stored in a barn at Eastport, Me., for two or three months and then shipped to Washington, D. C., for use in the feeding experiments reported in this bulletin, this fish meal was found to contain water 4.74 per cent, protein (N×6.25) 60.50, fat 14.56, crude fiber 0.61, ash 16.68, and salt (NaCl) 5.78.

In feeding tests by the Dairy Division of the Bureau of Animal Industry, dairy cows fed fish meal gave a greater yield of milk than those fed cotton-seed meal. The total milk fat from the two groups was about the same. There was some variation in the readiness with which the animals ate the ration containing fish meal. The meal had no detrimental effect on either the milk or butter.

Feeding experiments upon the value of fish meal for laying hens and for growing and fattening pigs were conducted by the Animal Husbandry Division of the Bureau of Animal Industry. In a comparison of fish meal with meat meal for laying hens, A. R. Lee reports that the lot fed the ration containing

fish meal laid an average of 113.1 eggs per hen in 32 weeks, and those fed a similar ration but containing beef scrap instead of fish meal averaged 128.4 eggs per hen. The hens ate the beef scrap a little more freely than they did the fish meal. No differences were noted in regard to size or flavor of eggs or the health and weight of the fowls.

In comparing fish meal with digester tankage (60 per cent protein) as supplements in a ration for pigs, F. G. Ashbrook reports that 12 grade Berkshire pigs averaging about 52 lbs. per head were divided into two lots and fed for 112 days, beginning January 19, 1915. The 8 pigs fed corn meal, middlings, and tankage (4:4:1) made an average daily gain per pig of 1.25 lbs. at a cost of 5.58 cts. per pound of gain, the average grain eaten daily per pig being 4.53 lbs. The 4 pigs fed corn meal, middlings, and fish meal (4:4:1) made an average daily gain per pig of 1.31 lbs. at a cost of 5.22 cts. per pound of gain, the average daily grain consumption per pig being 4.8 lbs.

At the close of the above period, May 11, 1915, the pigs were put on a ration for the fattening period, which lasted 28 days. The 4 pigs fed fish meal were continued on the same rations, and made an average daily gain per pig during the fattening period of 1.91 lbs. at a cost of 6.04 cts. per pound of gain and a daily grain consumption of 8.06 lbs. The 8 pigs previously fed tankage were divided into two lots of 4 pigs each. One of these lots was finished on a ration of corn meal and fish meal (9:1). They made an average daily gain per pig of 2.16 lbs. at a cost per pound of gain of 5.35 cts., their daily consumption of grain being 8.54 lbs. per pig. The other lot was fed corn meal and tankage (9:1). Their average daily gain was 2 lbs. per pig at a cost of 6.76 cts. per pound of gain, and they consumed 8.13 lbs. of grain daily per pig. In figuring the cost of gains in these tests, corn meal was valued at \$27 per ton, wheat middlings at \$30 per ton, digester tankage at \$50 per ton, and fish meal at \$35 per ton. It is stated that in these tests the hogs were extremely fond of the fish meal.

General directions for the manufacture of fish meal, opinions of stock-food manufacturers in reference to its use in the trade, and an estimate of the amount of raw material available for fish meal are given.

Cause and prevention of rancidity in palm nut kernel cake, R. B. CALDER (Jour. Agr. Sci. [England], 7 (1916), No. 4, pp. 470-472).—The author concludes from his studies that palm nut kernel cake, if kept dry and cool, remains sweet for at least ten weeks. If moist and warm it becomes rancid in a few days. The cake contains a zymogen which under the influence of warmth and moisture forms a lipase, which then turns the oil rancid. The lipase can be destroyed by heating the moistened cake to 70° C. (158° F.) for a short time. If the dry cake is heated the zymogen is usually destroyed, but dry heating is not so certain to destroy it as heating when moist.

Studies on the acidity of various feeding stuffs, L. Wilk (Ztschr. Landw. Versuchsw. Österr., 18 (1915), No. 8-9, pp. 485-558).—Data on the acidity of the following feeding stuffs are given: Pumpkin-seed cake and bran, sunflower seed cake, rape seed cake, linseed cake, peanut cake, molasses feed, sesame cake, rice meal, coconut cake, cotton-seed meal, palm-kernel cake, corn germs, dried beet foliage, potato pulp, and blood, meat, and fish meal. Methods of determining acidity are discussed.

Tricolor inheritance.—I, The tricolor series in guinea pigs, H. L. IBSEN (Genetics, 1 (1916), No. 3, pp. 287-309, figs. 4).—In this paper, reporting work at the Wisconsin Experiment Station, the factors more or less directly concerned with tricolor inheritance in guinea pigs are described and their interrelations shown.

In the experimental results it is shown "that tricolors may be of two kinds, those homozygous and those heterozygous for the  $e^p$  or black-spotting factor; that black-and-whites of tricolor parentage are also either homozygous or heterozygous for the same factor; and that red-and-whites of tricolor parentage may carry the  $e^p$  factor in a homozygous or heterozygous condition, or it may be altogether absent, in which event the red-and-white breeds true.

"Red-and-whites may be tested for the presence of the black-spotting factor by mating them to homozygous self reds. If the factor is present there will be tortoises among the offspring; if it is absent they will be all self reds.

"Black-and-whites of the tricolor series, homozygous for &, produce only tortoises when mated to homozygous self reds; if they are & half of the offspring are tortoises and the other half self reds. Both these kinds of black-and-whites, therefore, produce some tortoises, but no self blacks when mated to self reds.

"Black-and-whites carrying E may be of three kinds, EE,  $Ee^p$ , and Ee. The first kind when mated to homozygous self reds produce all self blacks; the second kind, half self blacks and half tortoises; the third kind, half self blacks and half self reds. Black-and-whites carrying E, therefore, always produce some self blacks when mated to self reds, but in some instances (when  $Ee^p$ ) also produce tortoises.

"EE and Ee black-and-whites were produced by mating self blacks to ee red-and-whites and inbreeding the  $F_1$  self blacks. Some of the  $F_2$  generation are black-and-whites which are either EE or Ee. The first kind when mated together breed true.

"Animals of the tricolor series carrying a large amount of black pigmentation  $(e^p)$  and also a large amount of white spotting tend to produce a comparatively large number of black-and-whites and no  $e^p$  red-and-whites. Those carrying a small amount of black pigmentation tend to produce a comparatively large number of  $e^p$  red-and-whites and no black-and-whites.

"The statement is made, but complete experimental proof is reserved for a later paper, that the three factors, E, complete extension of black pigment,  $e^p$ , partial extension, and e, nonextension, form an allelomorphic series."

A bibliography of literature cited is given.

Inbreeding in tail-female, W. H. E. WANKLYN (Bloodstock Breeders' Rev., 5 (1916), No. 2, pp. 140-142).—The author states that inbreeding to the male line has hundreds of prominent successes so far as to the female in her influence on future generations is concerned, while the results of inbreeding in female-tail can be counted in small numbers. Examples of successes in female-tail inbreeding are given.

Sex control and known correlations in pigeons, O. Riddle (Amer. Nat., 50 (1916), No. 595, pp. 385-410, fg. 1).—The author states that the studies that have thus far been made on sex and on the experimental control of sex in pigeons go very far toward an adequate demonstration that germs prospectively of one sex have been forced to produce an adult of the opposite sex—that germs normally female-producing have, under experiment, been made to develop into males, and that germs which were prospectively male-producing have been made to form female adults. Neither selective fertilization, differential maturation, nor a selective elimination of ova in the ovary can account for the observed results. Further, and perhaps of more importance, these studies throw much new light on the nature of the difference between the germs of the two sexes. This difference seems to rest on modifiable metabolic levels of the germs; males arise from germs at the higher levels, females from the lower; and such basic sex differences are quantitative rather than qualitative in kind.

The animal-breeding industry, R. Pearl (Sci. Mo., 3 (1916), No. 1, pp. 23-30).—A general article treating of the number and value of farm live stock in the United States, exports and imports.

Sheep management; breeds and judging, F. KLEINHEINZ (Madison, Wis.: Author, 1916, 3. ed., rev. and enl., pp. XX+306, figs. 111).—This is the third edition of this book, revised and enlarged (E. S. R., 26, p. 570).

The improvement of the sheep of the Middle Tiber Valley by means of crossing with Rambouillet Merinos, P. Pazzini (Staz. Sper. Agr. Ital., 48 (1915), No. 9, pp. 649-676; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 6 (1915), No. 12, pp. 1681-1683).—In these experiments it was found that compared with the native breed the crosses show better shape, greater weight of the lambs at birth, greater increase in weight of the lambs, greater carcass weight in the wethers, and greater chest index, together with a lower heart and lung index. Observations made on the production of wool show that the crossbreds have an additional advantage, both as to absolute weight of fleece and quality of fiber.

A new fleece record claimed, W. Stemmons (Breeder's Gaz., 69 (1916), No. 21, p. 1114).—It is claimed that the heaviest fleece ever shorn from a single sheep was recently taken from a 2-year-old Rambouillet ram on the farm of the Oklahoma Agricultural College. The fleece weighed 46.25 lbs. The fibers of the fleece were measured and found to average 1/1800 of an inch. The average length of the staple of this fleece was 3.25 in., and the average length of the fiber when stretched 5.25 in. This fact shows that the crimp is exceptionally good, and because of this the felting properties of the wool are extraordinary.

Mendelism of short ears in sheep, E. G. RITZMAN (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 20, pp. 797, 798).—The author describes a distinct type of short ears in sheep which in breeding experiments at the New Hampshire Experiment Station has behaved as a simple Mendelian unit factor, being dominant over long ears.

Corn silage for lambs, J. W. Wilson (South Dakota Sta. Bul. 165 (1916), pp. 377-390, figs. 7).—This bulletin gives results of two experiments involving 140 lambs, those for the 1914 test being home-grown or native lambs and those used in 1915 being western range lambs. Each fall there were 7 lots of 10 lambs each. The rations fed, the grain part of which was a mixture of corn and oats half and half by weight, and some of the results obtained are given in the following table:

Results of lamb-feeding experiments in 1914 and 1915.

		1914		1915	
Lots.	Average daily ration per head.	Daily gain per head.	Feed cost per pound of gain.	Daily gain per head.	Feed cost per pound of gain.
1 2 3 4 5 6 7	1.15 pounds grain, 1.38 pounds silage 1.52 pounds grain, 0.72 pound silage, 0.76 pound hay 1.62 pounds grain, 0.6 pound silage, 0.86 pound hay 1.49 pounds grain, 0.49 pound silage, 0.97 pound hay 1.51 pounds grain, 0.37 pound silage, 1.23 pound hay 1.52 pounds grain, 0.22 pound silage, 1.33 pounds hay 1.51 pounds grain, 1.11 pounds hay	. 25	Cents. 11. 44 8. 45 7. 12 7. 09 7. 96 7. 21 7. 45	Pounds. 0.08 .18 .23 .21 .19 .17 .16	Cents. 12.00 9.69 7.83 8.39 9.23 10.40 10.47

In figuring the cost of gain, grain was valued at \$20 per ton, silage at \$3 per ton, and prairie hay at \$6 per ton.

Tables are given showing individual weights and gains of lambs, as well as results of feeding experiments with lambs previously noted (E. S. R., 23, p. 176).

Self-feeding hogs, A. F. SAYRE (Country Gent., 81 (1916), No. 27, p. 1296).— In a feeding operation on a Wisconsin farm 59 spring and fall Duroc shotes were fed shelled corn by the self-feeder method for 35 days and made an average daily gain per head of 2.45 lbs., consuming 5.1 lbs. corn per pound of gain, and realizing a profit of \$61.65 on the lot. This amounted to a net feeding profit per bushel of corn of 14 cts., the cost of the corn being 68 cts. per bushel.

Feeding experiments with work horses, N. Hansson (Meddel. Centralanst. Försöksv. Jordbruksområdet, No. 126 (1915), pp. 54, figs. 3; abs. in K. Landtbr. Akad. Handl. och Tidskr., 55 (1916), No. 3, pp. 218-229; Jour. Bd. Agr. [London], 23 (1916), No. 3, pp. 275-277).—From these experiments it is concluded that 1 lb. of barley may be replaced by the following quantities of other foods for work horses: One and one-tenth lbs. mixed barley and oats, 1.2 lbs. oats, from 0.95 to 1 lb. corn, 1 lb. molasses, 1.1 lbs. sugar-beet slices, 1.2 lbs. wheat bran, 1.5 lbs. mixed oat bran and rice meal (3:2), 1.8 lbs. oat bran, 0.9 lb. dry matter in potatoes, and 1.1 lbs. dry matter in roots. Where considerable quantities of potatoes, roots, molasses, corn, etc., are fed additional protein must be given in the form of peanut cake, soy-bean cake, linseed cake, peas, beans, gluten feed, or good hay with clover, alfalfa, or other leguminous fodder.

The following are given as the requirements of work horses of 1,300 lbs. live weight, as regards digestible protein (pounds per head per day): Easy work, from 1.1 to 1.32 lbs.; moderate work, from 1.32 to 1.76; hard work, from 1.76 to 2.2; very hard work, 2.2 lbs. or more.

Sour milk for chicken feeding, H. L. KEMPSTER (Missouri Sta. Circ. 79 (1916), pp. 4, fig. 1).—Three 25-bird pens of White Leghorn pullets were fed from November 1, 1914, to October 31, 1915, to test the effect of sour milk on egg production. About two-thirds of the ration of each of the pens consisted of a scratch feed of corn and wheat (2:1). One lot which received no meat was fed a mash of bran, middlings or shorts, and corn meal; another lot was fed the same mash and in addition all the sour milk the fowls wanted; a third lot was fed the same mash with beef scrap.

The no-meat pen laid an average of 65 eggs per hen for the year, the beeffed hens an average of 107 eggs each, and the sour-milk-fed hens an average of 131 eggs each. On a cost basis per hundredweight for feeds of \$1.66 for wheat, \$1.60 for corn, \$1.20 for bran, \$1.70 for corn meal, \$1.40 for shorts, \$3.25 for beef scrap, and 20 cts. for sour milk, and, with eggs at 20 cts. per dozen, there was a loss of \$1 on the lot fed no meat, a profit of \$19.78 on the lot fed beef scrap, and a profit of \$28.26 on the lot fed sour milk.

Artificial brooding and chick feeding, W. F. SCHOPPE (Montana Sta. Circ. 56 (1916), pp. 193-207, figs. 8).—A description and working plans are given of a colony brooder house in which are installed two of the Maine fresh-air brooders (E. S. R., 26, p. 572). Directions for operating the brooder and feeding the chicks are included.

Fecundity of hens in relation to size of egg, E. Brown (Jour. Bd. Agr. [London], 23 (1916), No. 3, pp. 230-233).—Data taken from a laying competition, including 162 White Wyandotte pullets and 156 White Leghorn pullets, are given. The number of eggs laid by each pullet were divided into first grade (2 oz. and upwards), second grade (1.75 oz. to 2 oz.), and third grade (under 1.75 oz.).

In the case of the White Wyandottes the pen from which the highest number of eggs was obtained stood lowest but two in the percentage of first-grade eggs, the poorest of all in that respect standing third on the list as to number of eggs laid, while that which was lowest as regards the number of eggs was nearly the lowest also in point of first-grade eggs. On the other hand, the pen second in total number of eggs was also second in respect to size of egg. At the same time, with some exceptions, the figures in respect to size of egg favor the pullets, which were medium in fecundity. The mean of the breed in both directions to secure good marketable size, though the average is a low one, is from 800 to 900 eggs per six birds per annum.

With the Leghorns there was nothing to indicate that high fecundity is responsible for any diminution of the size of egg. The pen of Leghorns that was third in that breed was first in first-grade eggs (96.25 per cent), while the pen which was second in respect to first-grade eggs (95.56 per cent) was last save one in the total number of eggs laid.

It is stated that Leghorns are naturally more prolific than Wyandottes, and it may be expected, therefore, that forcing production will have a greater physical influence upon the latter, especially as the eggs are smaller than those of the former.

The ostrich-feather industry in South Africa, R. W. THORNTON (So. African Jour. Sci., 12 (1916), No. 7, pp. 272-279).—This article treats of the varieties of ostriches in Africa, their distribution, domestication, incubation, feeding, care, and management, clipping and quilling, and the marketing of feathers.

The breeding of "whitefish" (Coregonus spp.) in Switzerland, G. Surbeck (Schweiz. Fisch. Ztg., 23 (1915), No. 11, pp. 296-305; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 7 (1916), No. 1, pp. 112-114).—Artificial hatching and stocking of the lake herring or whitefish has met with success in Switzerland and is being encouraged. It is estimated that the weight of whitefish annually caught in the Swiss lakes is about 2,640,000 lbs. This represents a value of from \$400.000 to \$500,000, while the total gross returns from all species of fish from Swiss waters is estimated at somewhat over \$1,500,000.

#### DAIRY FARMING-DAIRYING.

The influence of the plane of nutrition of the cow upon the composition and properties of milk and butter fat: Influence of overfeeding, C. H. Eckles and L. S. Palmer (Missouri Sta. Research Bul. 24 (1916), pp. 3-39, figs. 4).—The investigations reported in this bulletin included four experimental periods and dealt with the influence of a supernormal plane of nutrition of cows upon the composition and properties of milk and milk fat. The cows used were a pure-bred milking Shorthorn in her fourth lactation period, a pure-bred Ayrshire in her fourth lactation period, and a pure-bred Jersey in her second and again in her third lactation periods. In the experiments the plane of nutrition varied from normal to plus 104 per cent. The grain and hay part of the rations, which was of the same character in all experiments, consisted of choice alfalfa hay and a mixture of corn chop, wheat bran, and linseed meal (4:2:1). The proportion of grain to hay varied in the different tests. In some cases the hay was supplemented by corn silage or by green alfalfa.

The experiments covered cases where a normal plane of nutrition prevailed previous to overfeeding and where the overfeeding was preceded by a subnormal plane of nutrition. It was found in both these cases that the most pronounced

result of overfeeding was to cause the cow to gain in weight, and that in none of the experiments did overfeeding exert an influence toward abnormality in composition of the milk or milk fat. In one case a high supernormal plane of nutrition prevented further changes in the constants of the milk fat due to declining lactation. In two cases where the composition of milk and the constants of the fat were abnormal, due to previous underfeeding, the result of overfeeding was to restore normality. The conclusion is reached "that normal milk and butter is to be expected when the cow is on a supernormal plane of nutrition as well as when the plane of nutrition is normal, provided there are no other influencing factors such as specific feeds."

Data obtained on the effect of overfeeding on milk flow indicate that the secretion of milk is regulated by at least two factors, designated as chemical and nervous. Facts brought out in the investigations are thought to show that the chemical stimulus, which is the stimulus that fixes the maximum milk flow and which is more or less independent of the plane of nutrition, is the predominating stimulus immediately following and for a period after parturition, but that as the lactation period advances the chemical stimulus gives way for the nervous stimulus. The nervous stimulus is dependent upon the plane of nutrition of the cow.

In one case only was there a marked increase in milk flow due to a superplane of nutrition. In this case the milk flow of the cow had been appreciably reduced by underfeeding. The results indicate, however, that a very high plane of nutrition is effective in holding off the decline in milk flow due to advanced lactation.

In two of the four experiments the percentage of fat was slightly affected by overfeeding. In one case there was a reduction of 0.2 per cent, but this accompanied an increased milk flow, the total fat production remaining practically constant. In the other case a high fat content due to previous underfeeding was restored to normal. With three of the cows the protein content of the milk, which in each case had been appreciably depressed, was restored to normality by overfeeding. In the other case intense overfeeding caused a constant high protein level of from 0.4 to 0.5 per cent throughout the entire period. This fell back to normal when the plane of nutrition was reduced. This increased protein percentage was accompanied by an increased milk flow.

The lactose percentage was the least uniformly affected by supernormal feeding. In the case of the Jersey cow, which started her lactation period in a very low state of nutrition and with an abnormally low lactose percentage in the milk, the lactose content was gradually raised to its normal value. The only effect of overfeeding on the saponification value of the milk fat was a strong tendency to produce a normal value. This was also true of the Reichert-Meissl number, the oleic acid content, and the melting point of the milk fat.

The influence of the state of nutrition on the composition of milk fat immediately following parturition is discussed.

Data connected with the experiments are tabulated in detail and shown graphically in the appendix.

The changes in composition of butter fat produced by feeding cotton-seed oil, F. H. SMITH, C. A. WELLS, and P. V. EWING (Georgia Sta. Bul. 122 (1916), pp. 95-111).—This is a detailed report of investigations previously noted (E. S. R., 35. p. 71) on the changes in composition which milk fat undergoes when the animal receives a ration containing cotton-seed oil, and on the transfer of food fat to the milk fat.

Two lots of two pure-bred Jersey cows each were fed a basal ration of silage, corn meal, and alfalfa hay from December 20, 1915, to January 16, 1916, when lot 1 was also given 0.5 lb. cotton-seed oil per head daily for two weeks, then increased to 1 lb. daily for two weeks, after which no cotton-seed oil was fed. Lot 2 received the basal ration throughout. Samples of butter from the mixed milk of each lot, morning and evening milking, were collected at the end of the second week of each period and at weekly intervals from the second week until the end of the test.

The milk fat from the two lots on the basal ration was almost identical in composition, but during the oil feeding period the saponification number for the fat of lot 1 decreased from 229.24 to 224.65, while with lot 2 there was little The soluble fatty acids decreased with oil feeding and the insoluble acids rose from 88.41 per cent to 89.3 per cent. The mean molecular weight of the insoluble acids increased from 259.06 to 264.75 during the oil feeding period. The mean molecular weight of the insoluble fatty acids of the cotton-seed oil was 292.8. The iodin number increased from 29.56 to 34.32 during the oil feeding period. The unsaponifiable matter in the butter remained practically constant throughout the experiment, and the variations in acid number, Reichert-Meissl number, and acetyl value were insignificant. With the Halphen test the fat of lot 1 showed a coloration corresponding to 0.5 or 0.6 per cent cotton-seed oil content during the period when 0.5 lb. oil was fed daily and 1 per cent oil content during the period when 1 lb. of oil was fed. The specific gravity of the milk fat was somewhat lowered and the melting point slightly raised while on the oil ration.

From these data the authors conclude that some change other than a simple transfer of cotton-seed oil to the milk fat had occurred. It was found that the addition of oil to the ration had the same general effect on the constants of the milk fat as an advance, in this instance, of five weeks in the lactation period.

"Cotton-seed oil, when fed in small quantities, was not transferred in any considerable amounts directly to the milk fat. Some of the substances of which the oil is composed apparently were transferred in a greater amount than others. The constituents of the oil did not reach the milk fat in those same combinations or proportions in which they exist in cotton-seed oil."

The more important literature pertaining to the subject is reviewed.

Important factors affecting machine milking, C. Larsen (South Dakota Sta. Bul. 166 (1916), pp. 394-421, figs. 9).—As a result of tests ranging from 7 months to 5 years and 3 months with seven makes of machines, the author points out factors other than the merits and demerits of different kinds of machines which have been found important in making machine milking a success. A comparison of the different makes of milking machines was not involved in these experiments.

In an experiment upon the germ content of machine-drawn milk the pail, rubber tubes, and all cups of a milking machine were thoroughly cleaned and scalded. The tubing and cups were kept in a disinfectant solution between milkings. The milk pail after being cleaned, rinsed, and steamed was kept in the milk room in an inverted position on a shelf between milkings. The average number of germs per cubic centimeter in the milk from the first cow with the machine was 5,325, from the second cow 3,017, and from the third cow 3,012. It is stated that thoroughly steaming the milk pails just before milking has been the means of greatly reducing the germ content of milk.

Results of experiments with disinfectants for the parts of milking machines showed that several substances are satisfactory, nothing being better for cheapness and simplicity than ordinary lime.

Studies on the numbers of bacteria present in milk which has undergone various changes, B. W. Hammer and R. H. Hix (lowa Sta. Research Bul. 29 (1916), pp. 35-62).—In the work reported an effort was made to secure information regarding the numbers of bacteria required to produce various changes in milk. While changes in the flavor and odor first attracted attention, other changes were considered because of the difficulties presented by all work dealing with changes in flavor and odor. Sterile milk was used for most of the work, although some experiments were carried out with aseptic milk.

The authors conclude that "from the data presented it appears that changes in milk due to the growth of bacteria therein occur only after large numbers of bacteria are present. The samples of milk which showed changes of one kind or another always contained over 1,000,000 bacteria per cubic centimeter and ordinarily much larger numbers. The sweet curdlers produced changes in milk with the smallest numbers of organisms, and here the smallest number observed with slight coagulation was 1,250,000 per cubic centimeter. With some organisms pronounced changes required approximately 1,000,000,000 per cubic centimeter, and between this value and the minimum already mentioned wide variations were encountered.

"Wide variations apparently exist in the numbers of organisms present in milk showing the same condition. This is evident from the percentage variation between the minimum and maximum and also by the results obtained when freshly inoculated cultures were plated at two-hour intervals for considerable periods. The difficulty of classifying the conditions observed in milk are, in part, responsible for the variations obtained.

"When Bacterium lactis acidi was inoculated into aseptic milk a distinct rise in acidity was commonly detectable by the sense of taste before the milk could be classed as sour. There seemed to be no definite relationship between the rise in acidity and the classification of the milk as sour or as showing a distinct rise in acidity. Acidity increases of 0.03, 0.04, or 0.05 per cent (in one case 0.02) were detected by the sense of taste, and this means that quite low acidities (acidities that would be regarded as normal) may be encountered along with acid flavors in the milk."

Some effects of temperature upon the growth and activity of bacteria in milk, H. S. REED and R. R. REYNOLDS (Virginia Sta. Tech. Bul. 10 (1916). pp. 3-26).—In this investigation upon the vitality of different species of bacteria in milk at different temperatures the factors studied were (1) the numbers of bacteria, (2) the proportion of acid-forming bacteria to others, (3) the changes affecting the consistency of the milk, (4) the quantity of acid formed in the milk, and (5) the reducing action as measured by the conversion of methylene blue. In securing pure cultures fresh milk was obtained from the college dairy, the cream separated, and samples of 100 cc. placed in Erlenmeyer flasks. The samples were sterilized fractionally by heating to 95° C. for 15 minutes on each of three consecutive days; they were then incubated for three days at 32°, and those which showed no signs of bacterial growth were given another fractional sterilization extending over three days. The samples were inoculated with a pure culture of the desired organism after the final sterilization and incubated at four different temperatures for a six weeks' period. During this time the multiplication of the organisms and their activity were studied at temperatures ranging from that employed in commercial milk storage to that of a warm summer day.

Results in detail are tabulated for each of the 13 organisms studied, a summary of which, showing the effect of age and temperature on bacterial growth, is given in the following table:

Effect of age and temperature on bacterial growth in milk.

Wind of annual trans	Age, in days, of milk kept at various tem peratures, which gave maximum counts on nu'rient agar.				
Kind of organism.	Incuba- tor, 35° C.	Room, 15-28°C.	Water tank, 13°C.	Cold stor- age, -1°C.	
Bacterium lactis acidi Sarcina lutea Bacillus coli B. cyanogenes B. proteus vulgaris. B. xrogenes B. fluorescens liquefaciens B. putidum Microspira tyrogena B. subitils M. citricus M. citricus D. didium lactis B. prodigiosis.	1 3 2 2 3 3 3 3 21 42	3 42 5 21 2 5 5 5 4 21 42 5 42 42 42	5 42 5 4 4 42 42 42 5 42 21 4 5	3 21 2 42 3 3 3 21 42 21 4 42 42	

All the organisms studied grew to some extent at the temperature of  $-1^{\circ}$ . Two types of micro-organisms were found very sensitive to this temperature. *B. lactis acidi*, representing one type, increased from 30 per cubic centimeter at the beginning to 2,870 per cubic centimeter on the third day, after which the members gradually decreased to 50 per cubic centimeter on the forty-second day. The other class, represented by *M. tyrogena*, grew very slowly at first but increased during the latter part of the observation period, reaching nearly 10,000 per cubic centimeter on the forty-second day. It is stated that this growth relationship has an important bearing upon the storage of milk at low temperatures for long periods. The milk might be appreciably changed in chemical composition yet remain sweet. Certain organisms commonly associated with filth, e. g., *B. fluorescens liquefaciens*, were more successful in growing at lower temperatures than the lactic acid bacteria.

"The temperatures of previous incubation appeared to have an influence upon the members of organisms developing upon gelatin and agar plates, as well as the optimum temperature for the different organisms. The members of organisms developing on agar plates were more or less closely correlated with the amount of acid formed and the curdling of the milk. The number of organisms developing on gelatin plates were more or less closely correlated with the formation of enzyms capable of reducing methylene blue."

Studies on the clarification of milk, B. W. Hammer (Iowa Sta. Research Bul. 28 (1916), pp. 19-32).—The results obtained in these studies show that plates poured from clarified milk commonly, although by no means constantly, revealed larger numbers of colonies of bacteria than plates poured from unclarified milk. Since clarifier slime contains large numbers of bacteria and contamination was practically excluded the increases in the number of colonies developing on plates were only apparent increases, due to the breaking up of clumps of organisms by the centrifuging. There was no definite relationship between the effect of clarification, on the one hand, and such factors as the original count, temperature of the milk, or the percentage of fat, on the other. It is concluded that whether there will be an increase or a decrease in the apparent number during clarification probably depends on the types of organisms and on the presence of clumps.

Fifty-one comparisons of the bacterial content of clarified and unclarified milk were made on samples showing less than 100,000 organisms per cubic centimeter. In 3 cases the bacterial content was not influenced by clarification,

in 14 cases it was decreased from 2 to 24 per cent (an average of 12 per cent), and in 34 cases it was increased from 2 to 256 per cent (an average of 41 per cent). For the entire 51 samples there was an average increase of 24 per cent. In 27 comparisons made on samples showing from 100,000 to 500,000 organisms per cubic centimeter, in 9 cases clarification caused a decrease of from 2 to 36 per cent (an average of 12 per cent), and in 18 cases an increase of from 3 to 187 per cent (an average of 43 per cent). In 14 comparisons made on samples showing over 500,000 per cubic centimeter, in 3 cases the bacterial content was decreased by clarification from 5 to 40 per cent (an average of 24 per cent), and in 11 cases increased from 4 to 102 per cent (an average of 29 per cent).

In 52 comparisons of the cell content, clarification caused a decrease of from 7 to 73 per cent (an average of 39 per cent). The average cell content of the unclarified milk was 297,481, and of the clarified milk 177,442 per cubic centimeter. The percentage of cells thrown out showed no relationship to the original cell content, the percentage of fat, or the temperature of the milk.

Large numbers of bacteria were found in all the samples of slime studied. In 11 tests on clarifier slime, using a 1-cc. sample, the counts ran from 31,000,000 to 1,445,000,000 per cubic centimeter, while on 36 samples of 1 gm. each the counts ran from 103,500,000 to 20,000,000,000 per gram. The cell content of clarifier slime also was constantly high. In 3 tests, using a 1-cc. sample, there were from \$30,000,000 to 1,120,000,000 per cubic centimeter, while in 36 samples of 1 gm. each there were from 565,000,000 to 1,295,000,000 per gram. Neither the bacteria nor the cells were constantly present in greater numbers in any part of the slime.

Clarified pasteurized milk gave larger numbers of colonies on agar plates than unclarified pasteurized milk in 14 cases out of the 21 tried, while in the remaining 7 cases the unclarified pasteurized milk gave the higher counts. The larger numbers of colonies from the clarified samples were ascribed to the breaking up of the clumps as a result of the clarification.

The clarifier slime showed a certain amount of dirt, even when the milk clarified was produced under conditions that must be regarded as much above the average, and masses of red blood cells were occasionally found even when the milk was produced under careful conditions.

The ratio between the pounds of milk clarified and the amount of slime was very variable. This is explained, to a certain extent, by the fact that the milk came from various sources and presumably was produced under very different conditions.

"Since in the majority of cases clarification (either with or without pasteurization) causes an increase in the apparent numbers of bacteria in milk, it is necessary that in the bacteriological control of milk supplies this fact be taken into consideration. The increase may be a large one but, since it is only an apparent and not a true increase, high counts on clarified milk should not be considered as serious as approximately the same counts on unclarified milk. Serious contamination from a clarifier is not an impossibility and must be considered in dealing with clarified milk, but high counts on clarified milk evidently have a different significance than approximately the same counts on unclarified milk, due to the breaking up of the clumps during centrifuging."

## VETERINARY MEDICINE.

Larkspur poisoning of live stock, C. D. Marsh, A. B. Clawson, and H. Marsh (U. S. Dept. Agr. Bul. 365 (1916), pp. 91, pls. 15, figs. 12).—This monographic work is divided into three parts. The first part (pp. 1-28) gives a historical summary and review of the literature, and discusses the alkaloids

of Delphiniums, the losses from larkspur poisoning, common names of larkspurs, species concerned in poisoning, and the detection of species in the stomach contents. Part 2 (pp. 28–59) presents the details of experimental work, and part 3 (pp. 59–84) is devoted to a discussion of the results obtained and the conclusions drawn.

The authors find that "it is rarely possible to recognize macroscopically larkspur material in the stomach contents of cattle. By means of microscopic sections of stems, however, not only can Delphinium be distinguished from other plants but groups of the genus can be distinguished from each other. The genus falls into six different types of stem structure.

"Experimental feeding of larkspur was carried on for three seasons at Mount Carbon, in Gunnison County, Colo. In this work four species of Delphinium were used which have been identified as Delphinium barbeyi, D. menziesii, D. andersonii, and D. robustum. A large number of animals was used in this work, including horses, cattle, and sheep. Similar feeding experiments were conducted during one season at Greycliff, Mont., on D. cucullatum and D. bicolor. These experiments showed that the larkspurs are poisonous to cattle and horses but not to sheep. Horses, however, in pastures or upon the range do not eat enough of the plants to produce any ill effects, so that losses of stock from larkspur poisoning are confined to cattle.

"The low larkspurs are poisonous during the whole life of the plants, but inasmuch as they disappear early in July, cases of poisoning are confined to the months of May and June. The tall larkspurs live through the summer season, appearing in early spring. They are most poisonous in their early stages. After blossoming the toxicity gradually diminishes and disappears and the plant dries up, although the seeds are very toxic. Most of the cases of poisoning in Colorado occur in May and June, with sporadic cases in July. In other localities where the larkspurs blossom later poisoning may occur as late as August or even September.

"While definite feeding experiments have been performed upon only a few species of larkspur, it may be assumed, from the knowledge of plant poisoning upon the ranges, that other species have the same properties as those experimented upon and that feeding upon them produces the same results. The experimental work and the autopsies showed a clearly defined line of symptoms and certain definite pathological results. The feeding showed that there was no marked difference in toxicity between the different species of larkspurs and that the quantity necessary to produce effects varied within rather wide limits, but that, generally speaking, a quantity equal to at least 3 per cent of the weight of the animal was necessary to produce poisoning.

"From somewhat extensive experimental work on antidotes it was found that beneficial results could be obtained by using, hypodermically, injections of physostigmin salicylate, pilocarpin hydrochlorid, and strychnin sulphate, followed by hypodermic injections of whisky when needed.

"Poisoning upon the range may be prevented in some cases by digging up the tall larkspur when the greater number of plants is confined to comparatively limited areas. In other cases the handling of the cattle in such a way that they will not have an opportunity to feed upon the larkspur may prevent losses. In the case of D. menziesii it is desirable that the cattle should be kept away from the ranges where this plant grows in abundance until about the first of July, when the plant dies. D. barbeyi loses its toxicity after blossoming, so that a range with this plant is safe for cattle in the late summer and fall. It should be remembered, however, that local and climatic conditions may delay the time of blossoming, so that no arbitrary date can be given when a range is safe. D. bicolor probably never grows in sufficient quantities to be dangerous

as a poisonous plant. Inasmuch as the experimental work seems to show quite conclusively that sheep may feed upon larkspurs with entire impunity it is desirable in some cases, where there is an especial abundance of larkspur, to use the ranges for sheep rather than for cattle or to combine sheep grazing and cattle grazing in such a manner as to keep the areas of low larkspur eaten down by the sheep."

A list of the more important literature relating to the subject and cited by the authors is appended.

Poisonous plants and stock poisoning on the ranges of Montana, D. B. Swingle and H. Welch (Montana Sta. Circ. 51 (1916), pp. 73-95, figs. 11).—This is a summary of information, prepared for the stockmen of the State, which describes the more important poisonous plants to be avoided.

The nature of the disease due to the exclusive diet of oats in guinea pigs and rabbits, C. Funk (Jour. Biol. Chem., 25 (1916), No. 3, pp. 409-416).—Investigations were undertaken to study the effect of feeding oats to rabbits, guinea pigs, and rats, with special reference to the effect of the addition of sodium bicarbonate and the action of antiscorbutics.

It was found that the symptoms that develop in rabbits fed on oats are due possibly to acidosis and not to scurvy, judging from the beneficial effect of sodium bicarbonate and the ineffectiveness of the antiscorbutics. Guinea pigs on the same diet are not influenced by the alkali and respond so slightly to the action of antiscorbutics that the identity of this condition with human scurvy seems doubtful. Rats can live on oats for a considerable time, but not on autoclaved oats, and young rats fail to grow on this diet.

The effect of benzene on the production of antibodies, L. Hektoen (Jour. Infect. Diseases, 19 (1916), No. 1, pp. 69-84, figs. 2).—In the experiments reported injections of a mixture of benzene and olive oil in doses of approximately 1 cc. per kilogram of body weight into rabbits, at about the same time that sheep blood was injected, greatly reduced the production of specific precipitin and lysin. In considerably larger doses the same effect was observed on the production of lysin in white rats. "The reduction of antibody formation under these circumstances is associated with grave lesions in the marrow, with leucopenia, and other changes characteristic of benzene intoxication, the leucocytes in the rabbit being of reduced phagocytic power."

It is indicated that in the dog 0.02 cc. of benzene per kilogram of body weight may cause a leucocytosis associated with an increase of lysin for goat corpuscles. The course of antigen in the blood appears to be the same in benzenized as in nonbenzenized rabbits.

The injection of benzene at the height of antibody production appears to have but little effect on the leucocytes of the blood, and its antibody content, the precipitin especially persisting longer and with more fluctuation than otherwise.

"Benzene may lower the resistance to infection by reduction (1) of antibody production, (2) of the number of leucocytes, and (3) of leucocytic activity. That benzene acts on elements that elaborate antibodies, and that the leucocytogenic centers are concerned in this elaboration, is indicated (1) in the rabbit, by the reduction of antibodies and of leucocytes and by the resistance to these effects when antibody production is at or near its highest activity as measured by the concentration of antibodies in the blood, and (2) in the dog, when suitable doses are given, by leucocytosis and increased formation of lysin."

The coexistence of antibody and antigen in the body, B. S. Denzer (Jour. Infect. Diseases, 18 (1916), No. 6, pp. 631-645, pls. 2, fig. 1).—From the work reported it is concluded that antigen and antibody both in the cells and in the blood may be demonstrated during a period of three weeks succeeding the injec-

tion of a foreign serum into a guinea pig. After about 17 days the antigen apparently disappears from the cells and blood. Antibody is demonstrable in the cells from the ninth day onward, and in the blood after the fourteenth day.

"The interrelations of these four factors are probably very complicated. For a period of several days all may coexist in the body." The earlier observation that after partial desensitization both antigen and antibody may be demonstrated in the cells has been confirmed.

See also a previous note by Weil (E. S. R., 34, p. 778).

The effects of vaccine sensitized with homologous immune serum, as compared with those of a nonsensitized vaccine: An experimental study, S. Kakehi (Jour. Path. and Bact., 20 (1916), No. 4, pp. 410-443, figs. 5).—From the investigation reported, using the Bacillus pseudotuberculosis rodentium, it was found that "the sensitized vaccine has one slight advantage in that the increase of temperature in injected animals is a little lower on the average than that produced by the nonsensitized, not only after the first injection, but also after succeeding injections."

In the use of the sensitized vaccine a much smaller loss of weight was observed than when the nonsensitized vaccine was used. No appreciable difference in the degree of immunity conferred by each kind of vaccine was noted, as about the same degree of resistance against various lethal doses was manifested by the animals when compared ten days after the last injection of vaccine.

"The production of antibodies in the serum, testable by agglutination and complement fixation, is much less with the sensitized than with the nonsensitized vaccine under the same conditions. Thus the estimation of these antibodies in vitro does not show the actual degree of immunity given by the former as compared with the latter."

A bibliography of 39 references to the literature cited is appended.

On Anaplasma-like bodies in the blood of vertebrates, Annie Porter (Ann. Trop. Med. and Par., 9 (1915), No. 4, pp. 561-568, figs. 10).—"Anaplasmata may occur in healthy and in anemic vertebrate blood. The structures, also called marginal points and peripheral coccus-like bodies, are probably of diverse origin. It is doubtful if they are organismal in nature. Anaplasmata have been found by me in warm- and cold-blooded vertebrates, wherein conditions such as herpetomoniasis and anemia occurred. Some of the bodies originate from the nucleus of the erythrocyte or erythroblast, under the influence of hemolysis. The Anaplasma-like bodies were basophilic, apparently composed of chromatin or of a substance giving a similar staining reaction, and were homogeneous in structure. They varied from 0.3 to 2  $\mu$  in diameter, often being about 0.5  $\mu$ . Binary and multiple forms, which might be interpreted as phases of division, were seen."

Some experimental researches on induced herpetomoniasis in birds, H. B. Fantham and Annie Pobter (Ann. Trop. Med. and Par., 9 (1915), No. 4, pp. 543-558, pl. 1).—"Herpetomoniasis can be induced in birds, for example, canaries (Serinus canarius), sparrows (Passer domesticus), and martins (Chelidon urbica), by feeding them on insects containing herpetomonads. Herpetomonas culicis from Culex pipiens and H. jaculum from Nepa cinerca have fatally infected birds when fed to them. Both flagellate and nonflagellate herpetomonads have been found in the internal organs of the infected host. The cycle of the flagellates in the avian hosts resembled morphologically that in the insects. The disease induced may run an acute or a chronic course. In the acute cases in our birds the flagellate form of the parasite was the more obvious at death. In chronic cases, nonflagellate forms of the parasite were more numerous.

"Natural herpetomoniasis of a pigeon has been recorded by E. and Étienne Sergent in Algeria. This affords a parallel case with the natural and induced herpetomoniasis in mice previously recorded by us.

"The flagellate stage of *Leishmania donovani* in vertebrates is now known, and that of *L. tropica* in man has been known for some time. The links completing the evidence that a Leishmania is morphologically a Herpetomonas are thus complete. Leishmaniases are really herpetomoniases (or leptomoniases) arising from herpetomonads of certain invertebrates. Members of all classes of vertebrates may be capable of acting as reservoirs of herpetomoniasis, and the virus may exist in a very attenuated condition and so be difficult of detection."

The cause of rat-bite fever, K. Futaki, F. Takaki, T. Taniguchi, and S. Osumi (Jour. Expt. Med., 23 (1916), No. 2, pp. 249, 250, pl. 1).—A report of a systematic study made of two cases of rat-bite fever which recently came under observation. An India ink preparation of the exudate of a swollen lymph gland of one of the patients, made according to the method of Burri, and a section of the excised lymph gland impregnated with silver according to Levaditi's method, both showed the presence of a spirochete somewhat larger than Spirocheta pallida but smaller than S. duttoni and S. obermeieri. Both patients recovered, one after treatment with mercury and the other with salvarsan.

Isolation and cultivation of Bacterium tuberculosis on a synthetic culture medium, C. A. Magoon (Washington Sta. Bul. 132 (1916), pp. 3-9).—The author reports some results obtained in a study of the metabolism of Bacillus tuberculosis by cultivating the organism on a culture medium of the following definite chemical composition: Ammonium phosphate (dibasic), 1.75 gm.; potassium phosphate (dibasic), 0.25 gm.; sodium phosphate (dibasic), 0.5 gm.; magnesium sulphate, 0.5 gm.; glycerin, 20 cc.; and distilled water, 1,000 cc. Special precautions necessary in the preparation of the medium are outlined in detail.

In preliminary tests to determine the suitability of the solution as a culture medium, B. subtilis, B. mycoides, B. prodigiosus, B. coli, B. cholera suis, B. pyocyaneus, and Staphylococcus pyogenes aureus all showed prompt and abundant growth. Inoculation of the medium with B. tuberculosis was followed by a vigorous growth which appeared in two days. Marked differences in the cultural characteristics of the bovine and human strains of the tuberculosis bacillus were noted as growth progressed.

In isolation experiments made from lesions of guinea pigs previously inoculated from a pathological laboratory culture of the bovine type positive results were obtained in 80 per cent of the trials made, the growth appearing in seven days from the time of inoculation. Pure cultures were also obtained in isolation experiments from the liver of a turkey spontaneously infected. Human strains of the micro-organism have been cultivated from lesions of guinea pigs inoculated with sputum with favorable results. While positive isolations have not been constant the work has been carefully checked.

"The practical value of this synthetic medium as a means of isolating the organism from tuberculous lesions is yet to be determined. As has been emphasized by other investigators the value of synthetic media in the study of the metabolism of the organism, and especially in the preparation of tuberculins free from heterogeneous albuminoids, is very great. Preliminary examinations of our rapidly growing cultures has shown them to possess marked antigenic properties, and their use in serological work shows much promise."

It is stated that investigations as to the value of these cultures in serum diagnosis are being pursued.

On certain reactions of the tubercle bacillus to sperm oil and its constituents, A. H. Miller (Jour. Path. and Bact., 20 (1916), No. 4, pp. 395-407, pl. 1).— The work reported confirms the earlier observation that the tubercle bacillus grown on sperm-oil media is converted into "banded" and "beaded" forms. The same conversion is also shown in its first stages of growth on an olive-oil medium. Such forms are not observed in bacilli grown on glycerin-egg, glycerinagar, cetyl alcohol, cetyl palmitate, and palmitic acid media.

It is deemed probable that the "banding" and "beading" is due, "in part at least, to the presence of unsaturated fatty acids in the form of esters."

Notes on the chemistry of sperm oil, by A. R. Smith, are included.

Tubercular antibodies and their rôle in the defense of the organism against tubercular infection, A. Calmette and L. Massol (Bul. Inst. Pasteur, 14 (1916), Nos. 2, pp. 33-40; 3, pp. 65-74; 4, pp. 97-104).—This is a general review of the subject, together with some experimental observations made by the authors, and is treated under the following topics: Preparation of a serum for research and the titration of the antibodies; choice and preparation of the antigen and determination of its value; antigenic properties of the organs, exudates, pus, and glandular excretions of tubercular subjects; researches on the titration of antibodies in the serum of tubercular patients; procuring a serum rich in antibodies; the inhibiting reaction of certain sera of hypervaccinated tubercular animals on the complement-fixation reaction; researches on the antibodies in the organ extracts and exudates of tubercular subjects; hereditary transmission of tubercular antibodies; the diagnostic and prognostic importance of the titration of the antibodies in tubercular infections; and the function of the antibodies in the defense of the organism against tubercular infection.

Protective inoculation of live stock in India, A. W. Shilston (*Agr. Jour. India*, 11 (1916), No. 2, pp. 112–133).—This article gives a short account of the initiation of prophylactic measures against animal diseases in India, and discusses the prevalence and treatment of rinderpest, hemorrhagic septicemia, true anthrax, black quarter of cattle and sheep, and tetanus.

Infectious abortion in cattle, W. GILTNER and E. T. HALLMAN (Michigan Sta. Circ. 29 (1916), pp. 13).—A summary of the present status of the knowledge of this disease of cattle and of control measures, prepared in response to a demand for information by dairymen of the State. The plan for control suggested by the authors is that of local treatment of the affected cow, disinfection, and sanitation.

The immunization of Egyptian cattle against rinderpest by simultaneous treatment with serum and virulent blood. Duration of immunity, Piot (Ann. Inst. Pasteur, 30 (1916), No. 4, pp. 187-194).—The author reports successful results of immunization tests with Egyptian cattle and recommends a systematic vaccination of cattle in all the Provinces of Egypt.

The procedure used in the simultaneous treatment and the clinical manifestations after the treatment are described in detail.

The immunity conferred in most cases was absolute, with a mortality in treated animals of less than 1 per cent.

The antigenic value of Spirochæta hyos in complement-fixation tests on hog-cholera sera. Studies on hog cholera, W. E. King and R. H. Drake (Jour. Infect. Diseases, 19 (1916), No. 1, pp. 46-62, figs. 5).—"Antigen prepared from S. hyos grown in pure culture possesses well-marked specific complement-binding properties. This antigen, when brought into contact with the sera of experimentally infected cholera hogs, produces initial complement fixation at a period coincident with completion of the incubation period as observed in clinical conditions and thermal reactions. The specific properties of the antigen are shown to be present until death of the animal, or until active immunity is fully

established. The sera of normal hogs and those experimentally infected with Bacillus cholera suis, the Ghon-Sachs bacillus, B. anthracis, Staphylococcus aureus, and also the serum of one hog which was the subject of pneumonia from natural exposure and which died from acute brine poisoning, all reacted negatively when tested for complement fixation with S. hyos antigen."

It is deemed that with the proper technique the method may be used to practical advantage as a reliable, accurate means of laboratory diagnosis of hog cholera. "The results of these experiments support our former conclusions that *S. hyos* merits serious consideration as an organism possessing specific pathogenic properties in relation to hog cholera."

Swine tuberculosis: Epidemiology, pathogeny, and comparative evolution, P. Chaussé (Ann. Inst. Pasteur, 29 (1915), Nos. 11, pp. 556-600, figs. 17; 12, pp. 633-647, figs. 5).—The author discusses the subject of swine tuberculosis in detail. Topics considered are the relative morbidity of bovine and porcine tuberculosis, paths of infection in swine, tonsillar and cervical lymphatic infection, intestinal infection, mixed infection, respiratory infection, tuberculosis through castration, the lesions in tubercular swine, a histological study of the lesions with special reference to the pulmonary lesions, and a comparison of swine tuberculosis with that of other species, especially in regard to the pathogenicity.

A study of gas production by different strains of Bacillus abortive-equinus, E. S. Good and L. S. Corbett (Jour. Infect. Diseases, 18 (1916), No. 6, pp. 586-595).—Continuing earlier studies at the Kentucky Experiment Station on the organism (E. S. R., 27, p. 580), it was found that in 93 out of 116 trials B. abortivo-equinus produced approximately 2 per cent gas in lactose and slightly less than 2 per cent in 28 out of 56 trials in saccharose.

The average gas production by the strain of *B. enteritidis* was about 2 per cent in lactose in 80 per cent of the trials and a slightly smaller amount in saccharose in 1 of 7 trials. The strain of the paracolon bacillus used in these experiments did not ferment lactose or saccharose.

"B. abortivo-equinus may or may not produce gas in 1 per cent lactose or saccharose broth, even varying in this respect in duplicate and triplicate tests. B. abortivo-equinus possesses as an original physiological characteristic the ability, in most cases, to ferment lactose to a small extent, and also, in some cases, to ferment saccharose to a less extent. This characteristic in all probability has not yet been accentuated by environment. Lactose and saccharose broth can be employed to good advantage in laboratory routine for differentiating B. abortivo-equinus from the colon bacillus, as the gas, when produced, is small in amount; and, in all probability, dulcite and perhaps raffinose can be used to advantage in differentiating B. abortivo-equinus from other members of subgroup 2 of the colon-typhoid group, but absolute proof as to its identity can only be secured through the use of other tests, such as those for further cultural characteristics and the complement-fixation and agglutination tests."

In the work reported the inverted vial was found to be as efficacious as the Smith fermentation tube.

Sclerostomes in horses, W. J. HARTMAN (Montana Sta. Circ. 58 (1916), pp. 221-236, figs. 8).—The author, having found this parasite to be a source of considerable loss in the Bitter Root and other valleys of the State, presents a general account of it and of the nature of the affection. It is thought that 95 per cent of the horses in the valleys are infected with the worms, though probably not more than one in ten develops noticeable symptoms.

Concerning nambi-uvu, a disease of dogs, and the causative parasite, Rangelia vitalii, A. Cabini (Centbl. Bakt. [etc.], 1. Abt., Orig., 77 (1915), No. 3, pp. 265-271, pls. 2).—The author describes a severe infectious disease of

dogs that occurs in Brazil and is commonly known as nambi-uvu, which appears in acute or icteric, subacute or hemorrhagic, and chronic or mild, forms. The disease is caused by R. vitalii, a parasite belonging to the family Piro-

plasmidæ.

Tuberculosis of poultry, H. Welch (Montana Sta. Circ. 57 (1916), pp. 209-219 figs. 7).—This circular discusses the subject of avian tuberculosis under the general topics of birds affected, nature of the disease, detection of the disease, post-mortem appearance, sources of infection, tuberculin testing, and eradication of tuberculosis.

#### RURAL ENGINEERING.

Hydraulics, R. L. DAUGHERTY (New York and London: McGraw-Hill Book Co., 1916, pp. XIV+267, figs. 245).—This is a brief treatise on the fundamental principles of hydraulics. It contains the following chapters: Introduction, intensity of pressure, hydrostatic pressure on areas, applications of hydrostatics, hydrokinetics, application of hydrokinetics, flow through pipes, uniform flow in open channels, hydrodynamics, description of the impulse wheel, description of the reaction turbine, water power plants, theory of the impulse wheel, theory of the reaction turbine, turbine laws and factors, and the centrifugal pump.

An appendix of tabular data is included.

Hydraulics and its applications, A. H. Gibson (New York: D. Van Nostrand Co., 1915, 2. ed., rev. and enl., pp. XVII+813, figs. 399).—This book is intended as a text-book for students and a reference book for practicing engineers, and deals with hydraulics and its application to the design of hydraulic machinery. It is divided into sections on the physical properties of water, hydraulics, and hydraulic machinery and contains 21 chapters on different phases of these subjects. An appendix of hydraulic tables and data is included.

Water power engineering, D. W. MEAD (New York: McGraw-Hill Book Co., 1915, 2. ed., pp. XVII+843, figs. 439).—This book covers the theory, investigation, and development of water powers. It contains the following chapters:

Power, the load, the flow of streams, the measurement of stream flow, a study of the power of a stream as affected by flow, pondage, storage, and head, water wheels, turbine details, and appurtenances, hydraulics of the turbine, turbine testing, turbine analysis and selection, speed regulation of turbine water wheels, the water wheel governor, arrangement of the reaction wheel, selection of machinery and design of the plant, examples of water power plants, the relation of the dam and power station, principles of construction of dams, appendages to dams, cost of power plants and of power, financial and commercial considerations, and the consideration of water power projects.

Practical methods of measuring flowing water, C. O. Wisler (Engin. and Contract., 45 (1916), No. 24, pp. 536-539).—"The object of this paper is to give a brief résumé of the different methods commonly employed in the measurement of flowing water, drawing attention to those purposes for which each method is best adapted and, finally, discussing in more or less detail some of the most important methods used in flow measurement."

Tests of loss of head in strainers, orifices, and sand, L. Pearse (Jour. Amer. Water Works Assoc., 3 (1916), No. 2, pp. 504-513, pl. 1, figs. 6).—The results of tests of the loss of head in strainers used in rapid filters and in small orifices are reported in tabular and graphic form.

Earth pressure, retaining walls, and bins, W. CAIN (New York: John Wiley & Sons, 1916, pp. X+287, figs. 99).—This book contains the following chapters: Laws of friction and cohesion-tables, direction, and distributon of stress; thrusts of noncoherent earth-graphical methods; noncoherent earth-analytical methods; designing retaining walls of stone or reinforced concrete; coherent earth; and bin theory. Two appendixes are included on stresses in wedge-shaped reinforced concrete beams and a discussion of experiments on model retaining walls.

Reports of the Board of Engineers Flood Control to the Board of Supervisors, Los Angeles County, California (Los Angeles: Bd. Engin. Los Angeles Co., 1915, pp. 400 pls. 21, figs. 189).—The text of the report, with maps, plans, specifications, and estimates, is given.

The laws of Indiana for constructing ditches and levees and on stream pollution and flood prevention, 1915 (Indianapolis, Ind.: State, 1915, pp. 368).—The text of the laws is given.

Surface water supply of Snake River basin, 1913 (U. S. Geol. Survey, Water-Supply Paper 362—B (1916), pp. 290).—This report, made in cooperation with the States of Idaho, Oregon, and Washington, presents the results of measurements of flow made on the Snake River and its tributaries during 1913.

Running water for farm homes, D. Scoates and J. W. Carpenter, Jr. (Miss. Agr. Col. Ext. Dept. Circ. 6 (1916), pp. 15, figs. 6).—This is a popular discussion with bills of material for four water-supply systems adapted especially to the needs of Mississippi farms. These vary in approximate cost from \$18.40 to \$128.80.

Sources of water pollution, J. W. Hill (Jour. Amer. Water Works Assoc., 3 (1916), No. 1, pp. 184-191).—The author discusses, from his own experience, the difficulties attending the selection of satisfactory sources of water supplies.

The latest method of sewage treatment, E. Bartow (Jour. Amer. Water Works Assoc., 3 (1916), No. 2, pp. 327-345, figs. 8).—This is a review of a number of recent reports of experimental work on the subject, many of which have been noted from other sources.

Sewage purification plants for small country residences and isolated buildings, A. P. I. Cotterell (Jour. Roy. Sanit. Inst., 37 (1916), No. 2, pp. 59-69, figs. 5).—The general features of the subject are discussed.

The utilization of ground waters by pumping for irrigation, G. E. P. SMITH ([Tucson, Ariz.: Author, 1915], pp. 31, figs. 7).—The purpose of this paper "is to present in brief compass a survey of modern irrigation pumping and a retrospect of the progress of the past ten years. [It] treats briefly of ground-water supplies, their occurrence, regimen, and recharge; of the methods of developing ground-water supplies by means of wells; of pumping machinery; and of the economics of this type of irrigation. It is a discussion of what is, and not of what ought to be; and a mention of new things rather than a description of the old."

Curves for irrigation-ditch velocity and discharge, L. R. Douglass (*Engin. News*, 76 (1916), No. 2, pp. 72, 73, figs. 2).—Two sets of curves are given which were prepared primarily for use in irrigation-ditch computation.

Some studies on the irrigation of citrus orchards, R. S. VAILE (Univ. Cal. Jour. Agr., 3 (1916), No. 8, pp. 329-332, figs. 3).—Studies of the amounts of water delivered to groves, including a comparison of distribution under various methods of application and culture, are reported.

It was found that "a very much higher efficiency has been obtained with the overhead irrigation than with the furrow irrigation," but the conclusion drawn from these results "would not necessarily be in favor of overhead irrigation as a general practice. It would rather be to point out the necessity for care in furrow irrigation."

Moisture determinations from composite soil samples of the first 4 ft. in clean cultivated and mulched portions of the same orchard showed "that 67476"—17——7

the maximum, minimum, and mean for the mulched section were all much higher than for the clean cultivated section. This was especially true in the earlier part of the season when the mulch was heavy. Later on, the straw became somewhat dissipated, and the moisture was not retained as well as earlier in the season. One considerable factor in the higher average under the mulch was that all of the ground was uniformly moist; while in the case of furrow irrigation the ground in the tree rows received very little benefit from irrigation."

Text-book of land drainage, J. A. Jeffer (New York: The Macmillan Co., 1916, pp. XX+256, figs. 95).—This book, prepared mainly for the practical farmer, represents an attempt "to put into simple and concise terms the fundamentals of our knowledge concerning the relation of water to agriculture and of the relation of drainage to soil water." It contains the following chapters: Characteristics of soils, physical interrelations in soils, humid areas and their reclamation, general drainage information, leveling, laying out a drain or system, construction, other conditions and problems, the hose level, using the hose level without leveling rods, drainage indications, drainage and the groundwater supply, drainage and climate, and drainage laws.

An appendix describes 18 experiments prepared to demonstrate some of the more important facts concerning soil conditions and drainage.

The drainage of white land and other wet lands in Oregon, W. L. Powers and T. A. H. Teeter (*Oregon Sta. Bul. 137 (1916*), pp. 80, figs. 43).—"This bulletin describes experiments to determine the most suitable depth, distance apart, and size for field drains in white land, and also gives information regarding the drainage situation in Oregon in general. There is in the State a great variety of wet lands of which three classes [predominate] namely, white land, marsh land, and alkali land. Drainage of much of this wet area appears to be feasible, as good quantities of plant food and friable layers have been found therein. . . .

"Studies of subsoil and ground water in white land generally show a friable streak at 33 to 36 in. depth and show also that tile placed in these areas have lowered the water table most promptly. The water table is lowered for 25 to 30 ft. back from the tile within 24 hours after saturation.

"A depth of 33 to 36 in. has been found most effective for lateral drains in typical white land, while deeper drains are desirable in the less retentive areas. An interval of 60 to 66 ft. between laterals affords the most practical drainage for typical white land under present conditions, and this distance may be increased in less retentive phases of this soil.

"Measurements of outflow indicate that main drains should have a capacity of  $\frac{1}{2}$  acre-inch run-off to the acre in 24 hours for areas up to 40 acres and  $\frac{1}{3}$  in. for larger fields. The total and percentage run-off in the Willamette Valley is large.

"Since drainage is costly and white land subsurface is retentive, farm operations should aim to aid water in entering the tile. When drained fields are in clover a larger outflow from tile and less surface water have been observed, and the structure and fertility of the land gradually improves.

"Reports from farmers having over 100 miles of tile in operation in the white land and other wet land in the valley show that tiling has generally been successful. The tendency is toward larger tile in place of small open ditches. A combination of tile with a surface run is good practice. Nature has determined the general location of ditches, and the size of the natural channel is an index to the required capacity. The grade should be low enough to receive the discharge from all laterals."

Important features of the state drainage law are also noted.

Blasting ditches, H. E. MURDOCK (Montona Sta. Circ. 55 (1916), pp. 185-192, figs. 7).—This circular gives dara secured on blasting open drainage ditches on the station farm at Bozeman, Mont. The soil is very gravelly and contains many large rocks, making digging difficult and expensive.

"In the blasted ditch two sticks of 60 per cent dynamite were placed in holes 22 in, apart. This distance was determined by experimenting to be the most desirable for the soil conditions. When the holes were spaced 22 in, or less ordinarily only one charge was needed for a primer, as the others would be exploded by concussion. When spaced farther apart some holes would mis-fire, When spaced less than 22 in, there was a waste of dynamite, as there was no additional benefit to the ditch. The holes were driven by tool-steel bars 2.5 ft. long. . . . In the work done in 1914 the holes were spaced 20 in, apart and electric caps and a blasting machine were used."

"A comparison of three lengths of ditch constructed in 1915 is as follows: Fourteen rods of hand-dug ditch cost \$3.35 per rod, 17 rods of blasted ditch \$3.10 per rod, and 39.2 rods of blasted ditch \$2.36 per rod.

First biennial report of the state highway commission [of Idaho] for the period ending December 31, 1914 (Bien. Rpt. State Highway Com. Idaho, 1 (1914), pp. 81, pls. 25, fig. 1).—The work and expenditures on roads in Idaho for the biennium ended December 31, 1914, are reported.

Annual report of the highways division [of Nova Scotia] for the year ended September 30, 1915, H. Donkin (Ann. Rpt. Highways Div. Nova Scotia, 1915, pp. 97, pls. 9, fig. 1).—Data on the work and expenditures on roads in Nova Scotia for the year ended September 30, 1915, are presented in detail.

Constitution and statutes of the State of Oregon relating to roads, highways, bridges, and ferries, compiled by B. W. Olcott (Salem, Oreg.: State Print. Dept., 1915, pp. 221).—The text of the legislation is given.

A handy road chart, N. G. Near (Engin. and Contract., 46 (1916), No. 1, p. 21 fig. 1).—A chart for the use of road builders in determining the number of square yards in any road up to nearly 2 miles in length and in any width up to 1,000 ft. is given.

Minimum tire widths for good roads, H. L. Hock (Cornell Civ. Engin., 24 (1916), No. 9, pp. 469-475, figs. 3).—In a brief review of the laws and technical data on the subject the author recommends "the adoption of a law which shall permit a maximum load of 250 lbs. per inch width per tire, if the tire is of wood, metal, or other hard material; and 300 lbs. per inch width per tire if of rubber or other resilient material."

Some comparative tests of wire-cut-lug and repressed paving brick, W. A. Goss (Engin. and Contract., 46 (1916), No. 1, pp. 8-11, figs. 2).—Abrasion, standard abrasion, standard absorption, specific gravity, cross bending, compression, shear and impact tests conducted at the University of Wisconsin on wire-cut-lug and repressed paving brick, are reported.

"The determinations arrived at as a result of these tests are that the wirecut-lug bricks have better abrasive and wearing qualities, greater density, greater crushing strength; the repressed brick have greater weight per unit volume, greater toughness. . . . In addition the wire-cut-lug brick are of more uniform quality than the repressed.

"The tests show that both types of the brick tested were of good quality for paving purposes. Either brick is plenty strong and tough enough for use in a pavement. The difference in wearing qualities and in uniformity are the most important determinations of these tests, and in these characteristics the wire-cut-lug brick have shown superiority. This difference is not marked, however, and it would be necessary to test out brick from other plants before one could state just what degree of difference exists."

Strength and other properties of concretes as affected by materials and methods of preparation, R. J. Wig, G. M. Williams, and E. R. Gates (U. S. Dept. Com., Bur. Standards Technol. Paper 58 (1916), pp. 172, pls. 2, figs. 44).— The results of about 20,000 tests, consisting of compressive and tensile tests upon mortars at different ages including about 240 different sands and stone screenings, and compressive tests on concretes composed of 60 aggregates including limestones, gravels, granites, cinders, and trap rock, are reported together with tests of the physical properties of the sands, stone screenings, and coarse aggregates. The following conclusions are drawn:

"No standard of compressive strength can be assumed or guarantied for concrete of any particular proportions made with any aggregate unless all the factors entering into its fabrication are controlled.

"A concrete having a desired compressive strength is not necessarily guarantied by a specification requiring only the use of certain types of materials in stated proportions. . . . The compressive strength of a concrete is just as much dependent upon other factors, such as careful workmanship and the use of the proper quantity of water in mixing the concrete, as it is upon the use of the proper quantity of cement.

"The compressive strength of concrete may be reduced by the use of an excess of water in mixing to a fractional part of that which it should attain with the same materials. . . . The compressive strength of concrete may be greatly reduced if, after fabrication, it is exposed to the sun and wind or in any relatively dry atmosphere in which it loses its moisture rapidly, even though suitable materials were used and proper methods of fabrication employed. The relative compressive strength of concretes to be obtained from any given materials can be determined only by an actual test of those materials combined in a concrete.

"Contrary to general practice and opinion the relative value of several fine aggregates to be used in concrete can not be determined by testing them in mortar mixtures. They must be tested in the combined state with the coarse aggregate.

"Contrary to general practice and opinion the relative value of several coarse aggregates to be used in concrete can not be determined by testing them with a given sand in one arbitrarily selected proportion. They should be tested in such combination with the fine aggregate as will give maximum density, assuming the same ratio of cement to total combined aggregate in all cases.

"No type of aggregate such as granite, gravel, or limestone can be said to be generally superior to all other types. There are good and poor aggregates of each type. By proper attention to methods of fabrication and curing, aggregates which appear inferior and may be available at the site of the work may give as high compressive strength in concrete as the best selected materials brought from a distance, when the latter are carelessly or improperty used.

"Density is a good measure of the relative compressive strength of several different mixtures of the same aggregates with the same proportion of cement to total aggregate. The mixture having the highest density need not necessarily have the maximum strength, but it will have a relatively high strength.

"Two concretes having the same density, but composed of different aggregates, may have widely different compressive strength. There is no definite relation between the gradation of the aggregates and the compressive strength of the concrete which is applicable to any considerable number of different aggregates. The gradation curve for maximum compressive strength, which is usually the same as for the maximum density, differs for each aggregate.

"With the relative volumes of fine and coarse aggregate fixed, the compressive strength of a concrete increases directly, but not in a proportionate ratio as the cement content. An increase in the ratio of cement to total fine and coarse aggregates when the relative proportions of the latter are not fixed does not necessarily result in an increase in strength, but may give even a lower strength.

"The compressive strength of concrete composed of given materials combined in definite proportions and fabricated and exposed under given conditions can be determined only by testing the concrete actually prepared and treated in the prescribed manner.... The compressive strength of most concrete as commercially made can be increased 25 to 100 per cent or more by employing rigid inspection, which will insure proper methods of fabrication of the materials."

The composition of the exhaust from liquid-fuel engines, R. W. Fenning (Jour. Inst. Mech. Engin. [London], No. 4, (1916), II, pp. 185-236, figs. 9; Gas Engine, 18 (1916), Nos. 5, pp. 242-258, figs. 6; 6, pp. 287-289, figs. 3).—With reference to the practice of analyzing the exhaust gases of internal combustion engines to determine the completeness of combustion and the probable strength of the air fuel mixture supplied, a method of constructing exhaust gas charts for suitable fuels without the use of an engine is described and the results of numerous experiments relating thereto reported. The experiments consisted of a comparison of the composition of the products of combustion of prepared mixtures of air and vaporized fuel in known proportions exploded in a small vessel with the composition of the exhaust gases from an internal-combustion engine.

From the results of these experiments it is concluded that "with volatile fuels there is but little difference in the composition of the products of combustion resulting from air-fuel mixtures in a small explosion vessel or in an engine cylinder in spite of the conditions being so dissimilar. The agreement between the CO₂, O₂, and CO values in engine and explosion vessel tests is so close that an exhaust gas chart prepared from explosion vessel tests can be used to estimate the strength of mixture supplied to an engine. A very small quantity, if any, of unsaturated or saturated hydrocarbons is present in engine exhaust gases. Taking a particular instance, methane is almost entirely absent. The hydrogen constituent in exhausts from strong mixtures is an important item and increases in value rapidly with increase in mixture strength. The ratio of air to fuel in the original mixture can be calculated with a considerable degree of accuracy from the composition of the exhaust gases."

[Tractor specifications], P. S. Rose (Amer. Thresherman, 19 (1916), No. 3, pp. 1-4, 6, figs. 2).—A table of specifications for 144 tractors of 91 different makes is given, together with two diagrams showing arrangements of tractor wheels and styles of motors.

[Drawbar pull of tractor], R. Olney (Power Farming, 25 (1916), No. 5, pp. 7-9, figs. 2).—This article discusses the drawbar rating of tractors in terms of horsepower and gives a set of curves and a table of data showing tractor speed in miles per hour, drawbar pull in pounds, and drawbar horsepower

pounds pull X speed in miles per hour

based on the formula Horsepower =-

375

The construction of the dairy house, H. A. RUEHE (Illinois Sta. Circ. 188 (1916), pp. 8, figs. 4).—The general principles to be followed in dairy house construction and equipment are presented by discussion and diagrammatic illustrations,

How to build a hollow tile silo (*Brick and Clay Rec.*, 48 (1916), No. 12, pp. 1116-1118, figs. 5).—Instructions, with diagrammatic illustrations, for this work are given.

Poultry houses for Georgia, R. F. IRVIN (Bul. Ga. State Col. Agr., No. 96 (1915), pp. 8, pls. 4, figs. 5).—This bulletin points out the general requirements of a good poultry house and describes and illustrates three types designed with reference to Georgia conditions.

The Missouri poultry house, H. L. Kempster (Missouri Sta. Circ. 80 (1916), pp. 8, figs. 5).—This circular describes and illustrates the Missouri poultry house, giving bills of material and costs.

"Since the average farm poultry flock in Missouri is from 100 to 150 hens, this house is 20 ft. square, the square house being the most economical to construct and affording a maximum amount of floor space. The ridge of the roof runs north and south, the roof being of equal spans. The walls are 5 ft. at the eaves. It is 11 ft. high at the peak. The south side contains a door in the center and a window 2 by 3 ft. on each side of the door. These windows are placed high enough to afford a 30-in, opening beneath, 1 ft. above the floor and extending the entire length each side of the door. This opening is covered with wire screen, which keeps the hens in and the sparrows out."

Details of a trap nest are also included.

#### RURAL ECONOMICS.

A preliminary study of the marketing of Burley tobacco in central Kentucky, C. D. Bohannan and D. P. Campbell (Kentucky Sta. Bul. 202 (1916), pp. 157-244, pls. 8, figs. 10).—This is the first of a projected series of studies on the marketing of Kentucky farm products.

The culture and curing of Burley tobacco, which is now the greatest cash crop of the blue grass region, is briefly explained, the methods of marketing described in detail, and the relative profits of those handling the crop discussed

"Formerly the tobacco was shipped in hogsheads to Louisville or Cincinnati or sold in the barn to the buyer for one of the tobacco companies. Now it is, as a rule, sold at auction over the loose-leaf floors, although some crops are purchased in the barns by speculators.

"The greater part of each season's crop, of which during the last season 35.000,000 lbs. were sold in Lexington, is purchased by the agents or 'buyers' for the large tobacco manufacturers. . . . After sale to a buyer or broker the leaf is usually repicked, redried, and prized into hogsheads for shipping or storage."

The loose-leaf system is stated to be the most economically efficient system yet devised. It is, however, "susceptible of improvement in elimination of waste product and duplication of effort. From the standpoint of both grower and manufacturer there is much need of improvement in curing methods and in the grading of the leaf as it comes from the stalk. . . .

"Proper grading applies with peculiar force to Burley tobacco. Approximately 60 per cent of the total amount of tobacco sold over the Lexington floors is capable of improvement by rehandling and resorting. This improvement would result in raising the price at least 2 cts. per pound."

The need of a state marketing law and the use of standard grades for all farm products, which permits of division into grades, and for standard receptacles for products sold in containers is set forth. "No product not graded in accordance therewith should be permitted to be exposed or offered for sale

ualoss specifically described as not graded or placarded in legible letters 'not graded.' To facilitate the plating of blame for improperly graded leaf, contract strippers should be required to obtain a license bearing a registered number and certifying to their ability in grading tobacco,"

Disadvantages of selling cotton in the seed, C. F. Creswell. (U. S. Dept. Agr. Bul. 375 (1946), pp. 18).—The results of an investigation confincted in Oklahoma in 1913-14 to ascertain the relative advantages and disadvantages accrula; to the farmer from selling seed cotton instead of marketing the seed and the baled lint separately are reported. A study was made of 8.4 104b, samples collected from as many different loads sold by different farmers in ninger-presentative seed-cotton markets. The samples were ginned and carefully graded, and the results obtained are tabulated and discussed.

The examination of the samples indicated that the average lint outturned for the season in the districts covered by the survey was approximately 31.5 per cent. The seed cotton samples secured in the nine different towns showed an average variation of 14.3 per cent in lint, 27.5 per cent in seed, and 25.2 per cent in trush content. Tables are given showing that wide variations in qualities and outturns of seed cotton exist in the same market on the same day, and that these variations result in marked inconsistencies in equivalent lint prices when a uniform price is paid for seed cotton regardless of its quality. It is further shown that the custom of selling seed cotton resulted in wide variations between the prices received for the same quality of lint cotton in the same market during the same week.

Observations on the prices for each grade during the season throughout the State showed a loss on each grade when the cotton was sold unginned, the isos being larger on the higher grades than on the lower ones. A comparison by months between prices secured for cotton when sold unginned and when sold in the bale during the entire season in the markets represented, indicate a loss for each month ranging from an average of \$3.85 per bale in October, to \$10.25 per bale in December. The average baled lint price for the entire season was 11.7 cts., and the average equivalent lint price for the entire season 10.2 cts.

In a study of conditions in a specific locality it was found that \$3.95 more per bale was paid for Triumph than for other cotton. It is pointed out that on each pound of cotton sold unginned in this market the growers sustained an average loss of 1.01 cts., or \$5.05 on each bale.

The supply and price of wheat, H. HITIER (Ann. Sci. Agron., 4. ser., 4 (1916), No. 10-12, pp. 254-273).—The author discusses the production and consumption of wheat in the principal producing countries and the prices at the principal market centers for 1915, with comparisons for earlier years.

Foreign trade in agricultural products, 1913, O. Bobdiga (Atti R. Ist. Incoragg. Napoli, 6. ser., 66 (1914), pp. 35-77).—This report compares the imports and exports of agricultural products for 1913 with earlier years as to source, destination, and kind.

The system of land registration in New Zealand, G. G. Bridges (Internat. Inst. Agr. [Rome], Internat. Rev. Agr. Econ., 7 (1916), No. 4, pp. 92-112).—This article gives a general description of the methods used in conveying land, including the system of transfer, registration of dealings, attestations of instruments, and surveys, together with forms used in the different transactions.

Agricultural labor and wages (Lantarbetarnas Arbets-och Löneförhållanden inom olika Bygder och a typiska lantegendomar. Stockholm: Dept. Labor, 1915, pp. 412; rev. in Internat. Inst. Agr. [Rome], Internat. Rev. Agr. Econ., 7 (1916), Nos. 2, pp. 113–125; 3, pp. 106–123; 4, pp. 113–117).—This is a special report concerning agricultural laborers in Sweden, and discusses the classes of holdings, types of farming, number and distribution of the agricultural popula-

tion, terms of employment, wage systems, grants of land to agricultural laborers, and labor conditions on certain typical holdings. Information is also given concerning the duration of work and the kind and rate of wages for the different classes of agricultural workers.

Farmers' cooperative electricity societies, C. L. Stewart (Wis. Country Mag., 10 (1916), No. 9, pp. 434, 435, 468).—The author states that the conclusion reached by cooperative leaders is that electricity societies should seldom build their own overland central stations, but that they should by all means be assured of sufficient custom. The average membership in societies owning their power works is between 300 and 400, and it is best for the membership to go into four figures if small farmers predominate.

Proceedings of the Seventh Provincial Conference of Cooperative Societies in Bengal (*Proc. Prov. Conf. Coop. Socs. Bengal*, 7 (1915), pp. II+74+XXXVIII, pl. 1).—Among the topics discussed at this conference, held at Calcutta in February, 1915, were those relating to the different phases of rural credit, cattle insurance, and cooperative dairying.

The rural home and the farm woman, D. B. Johnson (School and Soc., 4 (1916), No. 80, pp. 39-42).—The author states that "it is not sufficient to give the farm woman all of the conveniences of a model home. Country life must be made socially satisfying. In order for country life to be financially and socially satisfying the people must have education and own their homes, must cooperate with each other in rural community activities, and must have rural community organization for the promotion and support of an educational, religious, social, business, and intellectual community life."

Staircase farms of the ancients, O. F. Cook (Nat. Georgr. Mag., 29 (1916), No. 5, pp. 474-534, figs. 48).—In this article are described the type of agriculture, principal crops grown, and methods of managing the land practiced by the early inhabitants of Peru, as disclosed by a study of the remains of their hanging gardens and other prehistoric evidences.

Egypt of the Egyptians, W. L. Balls (New York: Charles Schribner's Sons, 1916, pp. XVI+266, pls. 33, figs. 2).—The author describes the methods of controlling the water of the Nile for irrigation purposes and its influence upon the agriculture of the country, the methods of growing crops, and the types of agricultural people.

Greater agricultural efficiency for the Black Belt of Alabama, C. E. ALLEN (Ann. Amer. Acad. Polit. and Soc. Sci., 61 (1915), No. 150, pp. 187-198, figs. 1).— The author compares the agricultural conditions in the Black Belt with the regions immediately adjacent where the whites are in the majority.

He points out that the Black Belt contains a soil more fertile and more adapted to the cultivation of staple crops, yet the average production of cotton per acre was 0.27 bale and 10.4 bu. corn in the Black Belt as compared with 0.34 bale and 11.4 bu., respectively, for the adjacent areas. In the "white" area the value of improvements is increasing more rapidly, more land is being brought into cultivation, and the rural population is increasing, while in the Black Belt there is a decrease in the area of cultivated land and in the rural population.

The author believes that the problem resolves itself into one of improving rural conditions of living so that rural life will become attractive by the establishment of improved highways, cooperative agencies, and better educational facilities, to be followed by efforts to teach the negroes scientific agriculture.

Farm management or what can be done on a fifty acre farm in east Texas, J. O. Allen (*Texas Dept. Agr. Bul., n. ser., No. 20, pp. 13*).—According to the author's plan, the 50 acres are to be distributed as follows: Ten acres in corn

and peas, 10 acres in cotton, 5 in oats, 2 in peanuts, 4 in hay meadow, 2 in orchard and peas, 6 in pasture for cows and horses, 4 in pasture for hogs, and 1 acre each in stock beets, garden and truck, Irish potatoes, sweet potatoes, strawberries, Sudan grass, and Ribbon sugar cane.

Instructions are given as to how to prepare the soil for the crops mentioned, how to seed, cultivate, and market the crops, and how to handle the pasture, stock, and poultry.

California resources and possibilities (Ann. Rpt. Cal. Develop. Bd., 26 (1915), pp. 64, pls. 2, figs. 5).—This report continues data previously noted (E. S. R., 33, p. 894).

Tennessee: Facts about soil, climate, and rainfall (Nashville, Tenn.: Dept. Agr., [1916], pp. 68, pl. 1, figs. 53).—Detailed information is given concerning the soil, climate, rainfall, and production of crops and live stock in Tennessee.

[Agricultural statistics of British Guiana], E. S. CHRISTIANI (Rpt. Dept. Sci. and Agr. Brit. Guiana, 1914-15, App. 6, pp. 18-22).—This report contains data showing the area and production of the principal crops from 1905-6 to 1914-15 by counties and districts.

South African agriculture: An analysis, P. J. Du Toit (So. African Jour. Sci., 12 (1915), No. 5, pp. 145-155).—In this analysis the author discusses the following factors affecting the agriculture of South Africa: Population, rainfall, transportation facilities, and types of agriculture based upon the principal products, such as sheep and wool and grain.

[Agriculture in New Zealand], M. Fraser (Statis. Dominion New Zeal., 3 (1914), pp. 1-47).—This continues data previously noted (E. S. R., 33, p. 193).

#### AGRICULTURAL EDUCATION.

Practical education—tomorrow's demand, L. W. Scott (Manual Training and Vocational Ed., 17 (1916), No. 9, pp. 665-673).—In this discussion the author attributes the shortcomings of our system of education largely to the failure of our schools to teach practical and utilizable knowledge. He concludes that the paramount issue of the school of to-morrow must not be preparation for college, but practical preparedness of every individual for life.

The effective use of the school farm: A record of an unfinished experiment, R. J. Teall (Manual Training and Vocational Ed., 17 (1916), No. 10, pp. 762-770, figs. 9).—An account is given of the field work, together with an outline of the 4-year course of study at the Gardena Agricultural High School, which is a part of the Los Angeles, Cal., city system, and is located 14 miles from the center of the city. In the construction of the course and in the development of plans for the proper utilization of the school farm it has been clearly kept in mind that (1) a boy, especially a city boy, preparing for agriculture must devote several hours daily to productive manual work; (2) practice and theory, like induction and deduction, must go together; (3) the science teaching of the school must be correlated with the applied courses; and (4) any high school courses, even a vocational course, should be a broad one.

The school began agricultural work in 1910, has about 15 acres for agricultural use, and has 70 boys in the agricultural course, less than 20 of whom are country bred, and few of whom have ground available for home-project work. Six city boys, twelfth-year students, are given their board and lodging on the grounds, and in return do all the miscellaneous work of the farm before and after school hours. Each half year a new set of boys is chosen.

In the tenth and eleventh years field-practice courses are offered in which the boys do on the farm that particular piece of work which is most urgent,

whether in horticulture or animal husbandry, etc. Courses are offered in horticulture, agronomy, dairying, poultry keeping, and animal husbandry, largely text-book courses, but all related to the general course called field practice. The classes in farm building construction have erected a dairy building, a garage and wagon house, a small house for an acetylene gas generator, a black-smith shop, and other small buildings, and with the assistance of two carpenters have constructed a good barn.

[Barrio school industrial efficiency contest], H. E. CUTLER ET AL. (Philippine Craftsman, 4 (1916), No. 7, pp. 429-496, figs. 29).—A résumé of the barrio school industrial-efficiency contest is given, followed by discussions of standards by which industrial efficiency is judged, and an account of the work of the trade schools, farm schools, settlement farm schools, primary gardening work, etc.

The barrio schools reported instruction in gardening to classes ranging from 8 to 45 pupils. In 80 per cent of the schools 5 recitations were held per week, and more overtime was given to this course than to any other, and it was considered the one which most influenced the home. The average school garden contained 457 square meters (about 4,917 sq. ft.) of land with an animal-proof fence. The pupils cultivated on an average about 23 square meters of land at school and 16 square meters at home.

The present trend of nature-study in Wisconsin, F. T. ULLRICH (Nature-Study Rev., 12 (1916), No. 3, pp. 102-115).—The author gives in detail the results of a questionnaire sent out as to the present trend of nature study in Wisconsin.

Systematic courses in nature study were presented in only 19 per cent of the 86 graded schools of the State reporting, but it was taught in an incidental manner in 24 per cent additional. The most frequent objections to or difficulties encountered in the presentation of systematic courses are overcrowded curriculum and dearth of qualified teachers for the instruction.

The majority of the replies state that the chief aims of nature study in the primary grades are to train the powers of observation, to develop the esthetic and appreciative capacities of pupils, and to acquaint them with the animate and inanimate material of their environment. The additional aims for the intermediate grades suggest special emphasis on training in the scientific method of thinking and the extension of the acquisition of information, and some educators think that a strong beginning should be made in the introduction of the economic elements into the instruction. In the grammar grades increased importance is given to the economic or vocational and the knowledge and preparatory aims.

The vocational aspect is presented in agriculture in three schools and in nature study in one. Even when agriculture is included with nature study the vocational in this subject is not very frequently attempted. There seems to be very little opposition to the idea of a vocational trend in nature study, although many believe that the cultivation of an appreciation of nature and nature's ways, may be defeated if the subject is over-practicalized.

The organization of nature-study, O. W. CALDWELL (Nature-Study Rev., 12 (1916), No. 5, pp. 189-192).—Information from nearly 400 school systems in Indiana and Illinois, which were taken as types, shows that something like 80 per cent of these schools are now teaching nature study, some in all of the eight grades, and practically all in at least four years. Less definite information from most of the other States indicates an essentially favorable situation, while in a few States very little attention is given to the subject. The need of organized courses and principles of organization are discussed.

What shall be our policy concerning gardening in the elementary city schools? C. D. Jarvis (Nature-Study Rev., 12 (1916), No. 4, pp. 174-178.—Productive gardening is discussed as one of the best available means of training children in habits of thrift and industry, developing stronger bodied children, making it possible for them to remain in school longer and contribute to the support of the family, etc. A plan for conducting the work is outlined, and the conclusion is drawn that garden work is of great benefit in the training of children in towns and cities; that the work should be conducted on an intensive businesslike and profitable basis, to insure which qualified teachers should be provided and retained throughout the summer, for groups of children not exceeding 200; further, that the work should be made so attractive that it will not be necessary to offer prizes to maintain the interest of the children.

A graded course of garden work and nature-study, R. W. Guss (Nature-Study Rev., 12 (1916), No. 5, pp. 213-225).—An outline is given of a course in garden work and nature study in the eight grammar grades and the first year of the high school in Cincinnati, in which an attempt is made so to grade the garden lessons and to correlate the nature study that each may help the other to educate the children through activities suited to their capacities and interests at different stages.

More than 500 children share the school garden of three acres near the school. In the first four grades the children have class or group plats, in the fifth and sixth individual plats, while in the seventh, eighth, and ninth grades the work is more optional and increasingly commercial or intensive (prevocational), larger areas being assigned to single applicants or to groups, usually for the growing of one crop. As a rule, these are pupils who have no land at home. Many of the children, however, have home gardens and the school gardens are used for learning gardening methods and as a laboratory for nature study and for growing nature study material. Much emphasis is laid upon summer supervision of both the school and the home plats.

Home gardens, G. B. Goldsmith (Nature-Study Rev., 12 (1916), No. 1, pp. 22-26).—The author discusses the value of home gardens for children, and suggests important considerations in flower and vegetable gardening.

Exercises in indoor gardening (for the use of schools), F. Watts (Imp. Dcpt. Agr. West Indies, Pamphlet 82 (1916), pp. [5]+48, pls. 10).—In this pamphlet the commissioner of agriculture for the West Indies outlines a series of practical exercises which may be carried out indoors so that discipline may be easily maintained. They are to be used in connection with the text, Nature Teaching (E. S. R., 17, p. 603), and are preparatory to the more extended work of the school garden itself.

### NOTES.

California University.—Dr. O. F. Burger, formerly assistant plant pathologist at the Florida Station, has been appointed instructor in plant pathology in the Graduate School of Tropical Agriculture at Riverside, and Alfred F. Swain assistant in entomology.

Kansas College and Station.—A country planning commission has been appointed by the state board of administration to meet the needs of rural communities. The board consists of eight specialists from the various state institutions, of whom five are from the college with Walter Burr, director of rural service work, as chairman.

Recent appointments include the following: Dr. M. C. Tanquary, assistant professor in entomology and assistant entomologist; R. K. Bonnett, assistant in farm crops; T. S. Townsley and F. E. Fox, assistants in poultry husbandry; A. E. Lawson, assistant in animal husbandry; D. H. Branson, animal husbandry assistant in extension schools; M. W. Kirkpatrick, superintendent of the Dodge City substation; Irwin T. Bode, foreman of the forest nursery at Hays; and Miss Dora M. Otto, research assistant to the director of the station. A. R. Losh, highway engineer in the extension division, has accepted a position with the office of Public Roads and Rural Engineering of the U. S. Department of Agriculture.

Nebraska University and Station.—The registration in the college of agriculture exceeds that of any previous year, taxing the accommodations in several departments.

Dr. A. R. Davis has been appointed assistant professor of agricultural botany, vice Miss Florence A. McCormick, resigned. E. L. Jenkins has been appointed instructor in animal husbandry.

Nevada Station.—Irrigation experiments have been particularly successful this year, owing to the fact that practically no rain fell during the entire summer, thus largely eliminating rainfall as a factor influencing the variations in yield.

Tests of anthrax serum, prepared by the method of Sobernheim, have shown the feasibility of making this serum by this method upon a commercial scale.

Cornell University and Station.—The faculty of the college of agriculture has been granted the privilege of electing two representatives to the state college council, with the right to vote. The council is an advisory body, reporting to the board of trustees, and the faculty has previously been represented thereon only by the dean. W. A. Stocking, jr., and J. G. Needham have been selected as the faculty representatives.

R. W. Rees, of the Massachusetts College, has been appointed extension professor of pomology; H. H. Knight, investigator in entomology; and C. B. Hutchinson, whose resignation from the Missouri University and Station has been previously noted, professor of plant breeding. Dr. Donald Reddick has been granted a year's leave of absence for special work in plant pathology at Johns Hopkins University.

Washington College.—D. S. Troy, of Chimacum, for 12 years a member of the board of regents and a prominent dairyman and Jersey breeder of the State, was killed August 18 in an automobile accident. J. P. Fairbanks, a 1916 graduate of the Nebraska University, has been appointed instructor in agricultural engineering.

Tenth National Dairy Show.—The first New England meeting of this show was held at Springfield, Mass., October 12-21, on the grounds of the Eastern States Agricultural and Industrial Exposition. All previous records for actendance, exhibits, and profits are said to have been broken. Nearly 1,000 entries of dairy stock were on exhibition and the attendance is estimated as averaging close to 30,000 per day.

Much prominence was given to educational features at the show. The U.S. Department of Agriculture gave special attention to its extension work among boys and girls, with several thousand exhibits of their work and many demonstrations by boys and girls illustrating methods in canning, bread making, dairying, selection of seed corn and potatoes, gardening, treatment of plant diseases, etc. A working dairy was also in operation by the Department.

The agricultural colleges of the vicinity cooperated in an eductional and agricultural display, each college concentrating its efforts mainly on some particular phase of the work. Thus Connecticut displayed a collection of forage crops, grasses, and root crops; Vermont depicted work in animal breeding; New Hampshire, farm management and accounts; Cornell, methods of teaching dairying; and Massachusetts, dairy manufactures and the care and handling of milk in the home.

The intercollegiate stock judging contest was participated in by eighteen institutions, many being represented for the first time. The highest rating for all breeds was attained by the University of Nebraska, with New Hampshire first on Ayrshires, Kansas on Guernseys, Massachusetts on Jerseys, and Nebraska on Holstein-Friesians.

There was also an intercollegiate butter-judging contest, arranged for the first time. In this contest, nine institutions were represented, first place being awarded to the Pennsylvania College.

Meetings of a large number of breed associations and other organizations interested in dairying were held during the show, that of the Official Dairy Instructors Association being noted below.

Official Dairy Instructors' Association.—This association met at Springfield, Mass., October 16-17, in connection with the National Dairy Show.

The presidential address was given by W. A. Stocking, jr., of Cornell University. Prof. Stocking emphasized, among other things, the need of higher standards and better preparation for men engaged in dairy work. Somewhat similar views were subsequently expressed at the annual banquet of the association by Dean C. E. Marshall of the Graduate School of the Massachusetts College, who urged that students be more broadly educated before being trained as specialists.

H. E. Rabild, of the Dairy Division of the U. S. Department of Agriculture, for the committee on methods of conducting student dairy cattle judging contests, gave a review of these contests showing the post graduate work and subsequent occupation of the successful contestants. The association voted to allow students who have participated in not more than one interstate judging contest to be eligible for the students' national contest, and to eliminate secondary schools from the contests except that, where there is no representation from the agricultural college of a State, students with certain qualifications from secondary schools directly under the supervision of the college may be admitted.

In a report as chairman of the committee on students' dairy products judging contests, W. P. Lockwood of the Massachusetts College stated that nine colleges and universities sent butter-judging teams to the first contest, held in connection with the Dairy Show. After a debate as to whether milk and cheese should be included in these contests, the committee was empowered to include as many products in next year's contest as it deemed wise.

A statistical review of milk and cream regulations was given by I. C. Weld, of Washington, D. C. The committee on legal limits for fat in ice cream was instructed to continue the work along the same lines. The committee on cream grading, to which one member was added from the Dairy Division, was directed to work out definitions for two or three grades of cream.

- H. C. Troy of Cornell University gave a report for the committee on official methods of testing butter for fat, in which he described two proposed modified Babcock methods and gave results obtained by these methods in comparison with those obtained by the official chemical method. This report was referred back to the committee for further study.
- H. H. Wing of Cornell University, for the committee on relations to breed associations, presented a report on official cow testing. Subsequently members of the association held a conference on the subject of this report with officials of the Ayrshire, Guernsey, Holstein-Friesian, and Jersey breed associations. After discussion the association voted (1) that the title of the person in charge of official cow testing in each State be the superintendent of official testing; (2) that the rules adopted by this association be published in pamphlet form and distributed to dairy testers; (3) that the different breed associations be asked to recognize the rules and regulations of the association in reference to official testing and to include them in their rules and regulations; (4) that the records of cow-testing associations be authenticated only when the official in charge of testing in the association is selected and appointed by the superintendent of official testing, and that this authentication of records shall be discontinued as promptly as some more satisfactory method shall be found; and (5) that the different breed associations be asked to recognize only one superintendent of official testing in each State.
- C. Larsen, of South Dakota, for the committee on feeding standards for milk production, discussed the different standards, the methods used by experiment stations and farmers for comparing the value of different feeding stuffs, and the use of the feed unit system. The committee recommended that no system be adopted by the association until present investigations on nutrition by the different stations are completed.

The executive committee was empowered to appoint members of the association to be members of a joint committee from this association, the International Milk Inspectors' Association, and the Association of Milk Dealers' on the matter of uniformity of inspection regulations by federal, state, and municipal authorities. Steps were also taken to revive the committee of the International Dairy Federation originally appointed by Major Alvord about 1895 with a view to creating a sentiment for getting the International Dairy Congress to meet in the United States. The executive committee was empowered to arrange for the publication of an official journal.

# RECENT WORK IN AGRICULTURAL SCIENCE.

#### AGRICULTURAL CHEMISTRY-AGROTECHNY.

Catalysis and its industrial applications, E. Jobling (London: J. & A. Churchill, 1916, pp. VIII+120, figs. 12).—The subject matter of this volume appeared originally in the Chemical World in 1912. The topics discussed are catalysis in general; sulphuric acid manufacture; industrial chlorin, salt cake, and sulphur recovery; fixation of atmospheric nitrogen; surface action; hydrogenation; dehydrogenation and oxidation; and dehydration, hydrolysis, etc.

Hydrogen electrode potentials of phthalate, phosphate, and borate buffer mixtures, W. M. Clark and H. A. Lubs (Jour. Biol. Chem., 25 (1916), No. 3, pp. 479-510, figs. 2).—The authors have studied the hydrogen electrode potentials of the following mixtures at 20° C.: Acid potassium phthalate—hydrochloric acid; acid potassium phthalate—sodium hydroxid; acid potassium phosphate—sodium hydroxid; boric acid+potassium chlorid—sodium hydroxid; boric acid—sodium hydroxid; and potassium chlorid at 25°—hydrochloric acid. The concentration of the first component was in all cases maintained at 5/100-molar strength.

It is suggested that "a temperature correction should be included in the barometric correction of hydrogen electrode potentials. The application of this, together with a consideration of several theoretical and experimental difficulties, leads to the conclusion that in biochemical work the tenth-normal KCl-calomel electrode should be given the provisional and somewhat arbitrary value 0.3385 between 18 and 30° when referred to the potential of the 'normal hydrogen electrode.' By applying the full barometric correction and the above value of the tenth-normal calomel electrode the  $P_H$  values of the various mixtures were calculated, and the compositions given which furnish mixtures differing by intervals of  $0.2P_H$  for use as comparison solutions in the colorimetric determination of hydrogen ion concentrations."

The system of "buffer" mixtures described has been shown to be simpler to prepare and easier to standardize than those now in common use. "Acid potassium phthalate solutions possess properties which make them comparable with or better than 'standard acetate' and similar solutions for standardizing hydrogen electrode systems."

A new "hot-air" Teclu burner, P. Verbeek (Chem. Ztg., 39 (1915), No. 148-149, p. 948, figs. 5).—A new laboratory burner in which the admitted air is heated before it is allowed to mix with the gas and in which the width of the flame can be easily controlled by a simple arrangement is described in detail. An economy in both heat and gas is claimed for the improved burner.

801

The action of nitric acid on aluminum, R. Selieman and P. Williams (Jour. Soc. Chem. Indus., 35 (1916), No. 12, pp. 665-672, figs. 3).—From a study of the action of nitric acid on aluminum the most important condition found to affect the rate of dissolution of the metal was the temperature of the acid. An increase of 10° C. over a considerable range of temperature was found sufficient to increase the rate of dissolution 100 per cent.

Next to temperature the concentration played the most prominent part in determining the rate of solution. Mixtures containing between 20 and 40 per cent by volume of nitric acid (specific gravity 1.42) were found to be the most active, while some samples containing as high as 94.7 per cent nitric acid were found to be almost without effect on the metal. A sample of aluminum suspended in such acid for 71 days lost only 0.0004 gm., equivalent to a rate of dissolution of 0.015 mg. per 100 sq. cm. per 24 hours.

Contrary to the statements of earlier investigators, the presence of 0.05 per cent chlorin in the acid was found not to affect the rate of solution. The same condition was found to prevail in the case of iodin up to concentrations of 0.01 per cent. Traces of sulphuric acid and the presence of the lower oxids of nitrogen, however, increased the rate of solution markedly. The action of the acid on the metal could be considerably reduced by freeing it from such oxids.

The effect of the physical state of the metal was considerable, the amorphous form being attacked much more readily than the crystalline. The composition of the metal was found to be of lesser importance, the pure metal, however, being generally found to be the most resistant to the attack of the acid. No local action or "pitting" was observed.

The apparatus and experimental methods used in the study are described in detail.

Sanitary studies of baking powders (Biochem. Bul., 5 (1916), No. 20-21, pp. 158-202).—The following studies on suitable analytical methods for the determination of small amounts of aluminum are reported.

II. A comparison of the method proposed by the Association of Official Agricultural Chemists as modified by Steel with that described by Schmidt and Hoagland for the determination of aluminum in organic material, P. E. Howe (pp. 158–164).—From experimental data reported it is concluded that, when compared to the results obtained with the procedure recommended by Schmidt and Hoagland,^a for small amounts of aluminum in the presence of iron and phosphates the method proposed by the Association of Official Agricultural Chemists as modified by Steel in an article previously noted (E. S. R., 25, p. 573) yields values which are essentially the same in the case of pure aluminum salts, but slightly lower when applied to blood to which aluminum sulphate has been added.

III. A study of the methods for the quantitative determination of aluminum in blood, L. J. Curtman and P. Gross (pp. 165-172).—The authors have found the method of Steel to be unreliable, due to the instability of ferric phosphate. For the determination of small quantities of the metal in the presence of large amounts of iron the method is unsatisfactory. The procedure of Schmidt and Hoagland yielded accurate results both in pure solution of aluminum salts and in blood.

It is indicated that the procedure of Schmidt and Hoagland is superior to that of Steel from the standpoint of technique for the following reasons: "(1) A direct gravimetric determination of aluminum is effected. No volumetric solution or operations are required and the aluminum is not found by difference (thus taking the sum of the errors). (2) The determination is made on the

^a Jour. Biol. Chem., 11 (1912), No. 4, pp. 387-391.

entire sample, not on an aliquot portion of the solution as in Steel's method and, as a consequence, the error in dealing with small amounts is thus materially decreased. (3) The tedium of washing the precipitates is to a great extent avoided without any sacrifice of accuracy."

IV. The determination of aluminum in the presence of iron and organic matter, M. Steel (pp. 173-182).—The author concludes that his method yields accurate results for aluminum when care is taken in its manipulation. "The method proposed by the U. S. Government Committee on Research and Analytical Methods is very similar to the method used by Steel. This method yields accurate results for aluminum, both in aqueous solution and in the presence of large amounts of organic matter. The Schmidt and Hoagland method is as accurate as the other two methods, and has the advantage . . . of involving fewer manipulations."

V. The determination of aluminum in biological material: A comparison of the method of Steel (modified by Kahn) with the method of Schmidt and Hoagland, C. A. Smith and P. B. Hawk (pp. 183-188).—The method of Schmidt and Hoagland was found by the authors to be more satisfactory than the method of Steel as modified by Kahn in work previously noted (E. S. R., 27, p. 268) for the determination of aluminum in blood and in gastric juice to which known amounts of aluminum had been added. In determining the metal in gastric juice by the Schmidt and Hoagland procedure it is indicated that the material should be ashed before the determination is made.

VI. Comment on the data in the preceding papers (II-V) on the best available method for the quantitative determination of aluminum in biological materials, W. J. Gies (pp. 189-194).—From a critical examination of the data presented in the previous articles the author concludes that "the Schmidt-Hoagland method is somewhat more accurate and serviceable than the Steel method for the estimation of aluminum in biological materials, and that the Steel method gives low results." Further comments on the work (reported in the previous papers) by the various authors are included.

VII. A direct test of the degree of accuracy of the Schmidt-Hoagland method for the quantitative determination of aluminum, A. K. Balls (pp. 195–202).— Experimental data submitted show that "the Schmidt-Hoagland method for the determination of aluminum gave results which involved a loss of as much as 7 per cent of the available aluminum, but which was usually about 4 per cent. The losses appear to have been due, in the main, to the formation of Al₂O₃ from AlPO₄, in the precipitate of the latter during ignition, but also partly to the solubility of AlPO₄ in the reagents and washings. The material, as finally weighed, is not wholly normal orthophosphate of aluminum, but contains less phosphoric anhydrid than does the same weight of orthophosphate. The indicated error might invalidate the method for accurate determinations of relatively large amounts of aluminum. For comparatively small quantities, however, the error appears to be negligible."

See also the first paper of this series by Gies, noted on page 860.

The determination of bromin and iodin in the presence of chlorids, L. W. WINKLER (Ztschr. Angew. Chem., 28 (1915), Aufsatzteil, Nos. 96, pp. 477-480, figs. 2; 98, pp. 494-496, fig. 1).—It is shown that by the use of potassium permanganate bromin can be accurately determined in the presence of chlorids. The procedure for the determination varies according to the amount of bromin present. For the accurate determination of very small amounts of bromin the free bromin extracted with carbon tetrachlorid is titrated with arsenious acid, using an aqueous iodin solution as indicator.

^a Jour Indus. and Engin. Chem., 7 (1915), No. 5, p. 446.

For the determination of iodin a number of methods were tested.

The experimental procedures and data obtained are described in detail.

A new method for the volumetric determination of thiosulphate in the presence of sulphid and notes on the determination of thiosulphate in the presence of sulphite, bisulphite, and sulphid, A. Sander (Chem. Ztg., 39 (1915), No. 148-149, pp. 945-947).—Three articles are presented.

I. Thiosulphate in the presence of sulphid (p. 945).—A new procedure based on the following equations, and which depends on titrating the hydrochloric acid formed, is described in detail:

$$3 \text{HgCl}_2 + 2 \text{Na}_2 \text{S} = 4 \text{NaCl} + (2 \text{HgS.HgCl}_2).$$
  
 $2 \text{Na}_2 \text{S}_2 \text{O}_3 + 3 \text{HgCl}_2 + 2 \text{H}_2 \text{O} = 2 \text{Na}_2 \text{SO}_4 + 4 \text{HCl} + (2 \text{HgS.HgCl}_2).$ 

The total thiosulphate+sulphid content is determined in an aliquot by titration with iodin. A second aliquot is treated with an excess of mercuric chlorid and well shaken until the dark precipitate becomes pure white. Ammonium chlorid is then added and the acid formed titrated with tenth-normal sodium hydroxid and methyl orange as an indicator.

II. Thiomulphate in the presence of sulphite (pp. 945, 946).—Earlier methods are briefly reviewed and criticized. The author obtained satisfactory results with the procedure of Bodnár (E. S. R., 31, p. 15), but indicates that it requires too much time for routine work. The determination of total sulphite+ thiosulphate by titration with iodin in an aliquot and the titration of the hydrochloric acid formed after treatment with mercuric chlorid in another aliquot is recommended as an accurate and rapid procedure.

III. Thiosulphate in the presence of sulphid and sulphite (pp. 946, 947).-Previous work is briefly reviewed and the following procedure outlined:

From 10 to 20 cc. of the sample for analysis is poured into a measured volume of tenth-normal iodin which has previously been acidified with from 5 to 10 cc. of tenth-normal hydrochloric acid, the excess iodin is titrated with tenth-normal thiosulphate, and the total sulphid+sulphite+thiosulphate (a) thus determined. In the same solution the iodin used by the sulphite is determined by titrating the hydrochloric acid formed with standard alkali (b), using methyl orange as indicator, due allowance being made for the hydrochloric acid previously added. Another portion of the sample is poured into an excess of mercuric chlorid, thoroughly shaken until the dark precipitate first formed becomes pure white, ammonium chlorid added, and the hydrochloric acid formed titrated with tenth-normal sodium hydroxid, using methyl orange. The reactions taking place are those noted above for the sulphid and thiosulphate and the following for the sulphite:

## Na₂SO₃+HgCl₂=NaCl+ClHg.SO₃Na.

In the thiosulphate reaction two molecular equivalents of hydrochloric acid are liberated by one molecular equivalent of thiosulphate, so that twice the volume of alkali (c) will be necessary for neutralization, as iodin was used in the first titration for thiosulphate. The various components are calculated from

data as follows: Iodin used for thiosulphate =  $\frac{c}{2}$ ; for sulphite, b; and for sul-

phid,  $a-(b+\frac{c}{2})$ . It is indicated that a determination can be made in 10 minutes and that the method is applicable in the presence of carbonate. In this case, however, a further titration with standard acid and methyl orange is necessary. Comparative experimental data demonstrating the accuracy of the method are submitted.

Determination of the hardness of natural waters, and the use of methyl red as an indicator, S. A. KAY and SUSAN H. NEWLANDS (Jour. Soc. Chem. Indus., 35 (1916), No. 8, pp. 445-447).—Modified procedures for the determination of both temporary and permanent hardness in water are described in detail. It is indicated that the proposed methods are more accurate than those now in common use.

Determination of calcium and magnesium in natural waters, S. A. Kay and Susan H. Newlands (Jour. Soc. Chem. Indus., 35 (1916), No. 8, pp. 447-449).—On the basis of certain preliminary experiments the authors have devised a method for the determination of calcium and magnesium by (1) determining the total hardness of the water, and (2) determining the hardness due to calcium salts by evaporating the water with ammonium carbonate and extracting the residue with ammonium carbonate solution, which dissolves the magnesium carbonate, but is practically without action on the calcium carbonate. The amount of the latter is then ascertained by titration, and the magnesium is determined by difference.

Analytical data obtained from mixtures of known composition indicate the accuracy of the method.

Salicylic acid in wine, X. Rocques (Ann. Chim. Analyt., 21 (1916), No. 6, pp. 117, 118).—The author observed that in certain natural wines some interfering substance which masked the color of the delicate ferric chlorid test for salicylic acid was present. This was later found to be tannin.

To obviate this possible source of error the following procedure is described: To 20 cc. of wine in a 250-cc. flask 0.5 cc. of sulphuric acid and, after thoroughly mixing, 15 cc. benzin are added. The flask is then stoppered and without agitation let stand until the next day. The salicylic acid is thus extracted by the solvent and, on separating the benzin layer in a separatory funnel, can be easily detected by the ferric chlorid test. This procedure will detect as small an amount as 4 mg. of salicylic acid per liter of wine very clearly.

The direct determination of sucrose in the presence of reducing sugars, M. A. SCHNELLER (Louisiana Stas. Bul. 156 (1916), pp. 12).—Experiments are described from which the conclusions previously noted (E. S. R., 35, p. 316) are drawn.

A comparison of the results obtained by the colorimetric and gravimetric determinations of cholesterol, J. H. MUELLER (Jour. Biol. Chem., 25 (1916), No. 3, pp. 549-560).—From a critical study of the two procedures for the determination of cholesterol it is concluded that either method is accurate when applied to solutions of pure cholesterol. The ether extraction with dried blood, even when prolonged, was shown not to be complete. Hot alcohol or alcohol and ether must be used. "Colorimetric analyses of blood give results too high for true cholesterol, because they include other ether- and chloroform-soluble substances, whereas digitonin determinations are more nearly correct."

A rapid method for the separation of butter fat from nonfatty material, S. Korpáczy (Ztschr. Untersuch. Nahr. u. Genussmtl., 30 (1915), No. 1, p. 24).— The usual method for preparing pure butter fat was found by the author to consume too much time and to be subject to certain sources of contamination. For the rapid preparation of pure butter fat the following procedure is recommended:

Forty gm. of butter and 10 gm. of pure, finely powdered calcined gypsum are thoroughly mixed in a porcelain dish. This homogeneous mass is allowed to stand for 10 minutes and is then placed in a drying oven where it is allowed to melt slowly, after which it is rapidly filtered through a dry filter. It is indi-

cated that by this procedure from 20 to 22 gm. of pure butter fat can be prepared in an hour.

The determination of the specific gravities of fixed oils in the Tropics, C. H. WRIGHT (Jour. Soc. Chem. Indus., 35 (1916), No. 8, pp. 457, 458).—Due to the fact that the dew-point of the air is usually about 15.5° C. (59.9° F.), it is a difficult matter to determine the specific gravity at this temperature in the Tropics, since moisture condenses on the outside of the apparatus used. A Westphal balance can be used if the oil is cooled to 15.5°, but the procedure is not convenient on account of moisture condensation on the surface of the oil and the platinum wire attached to the plummet. A convenient and rapid method in which the specific gravity is determined at the temperature of the air and then calculated for specific gravity at 15.5° is outlined in detail and the calculations for the same explained.

Peanut oil, H. C. Thompson and H. S. Bailey (U. S. Dept. Agr., Farmers' Bul. 751 (1916), pp. 16).—This is intended primarily for those interested in the manufacture of peanut oil or the growing of peanuts. It contains information regarding the manufacture of peanut oil in Europe and in this country, with reference to the preparation of the peanuts, the machinery used in peanut-oil manufacture, the by-products of the industry, and the economic aspects of the problems, such as yield, cost of production, and returns. Analyses showing the oil content of 12 samples of Spanish and 19 of Virginia varieties of peanuts, all grown in this country, and proximate analyses of the shelled nuts and shells of five varieties grown at Florence, S. C., are included.

Analyses of two oil fruits and seeds from tropical Africa, H. Wagner and J. B. Lampart (Ztschr. Untersuch. Nahr. u. Genussmtl., 30 (1915), No. 6, pp. 221-226, figs. 2).—The fruit of the plant Coula edulis is uniformly round and covered with an integument 5 cm. thick. The seeds themselves are white, with a very thin and brittle brown integument. The average weight of 100 nuts was found to be 1.463 kg. The sound seeds showed 12.01 per cent of protein, 30.48 per cent of fat, and 49.9 per cent of nitrogen-free extract.

The fat obtained was a brown liquid at room temperature and possessed no characteristic odor or taste. On analysis the following constants were obtained: Specific gravity (25° C.), 0.9116; index of refraction (40°), 51.2; acid value, 18.41; acid degree, 32.87; saponification value, 189.7; iodin value (Hübl), 83.36; Reichert-Meissl value, 0.36; and Polenske value, 0.22. For the total fatty acids the following values were obtained: Neutralization value, 197.5; average molecular weight, 284; iodin value, 87.09; and refractive index, 39.4. The phytosterol content was also determined according to the digitonin procedure and found to be 0.1623 per cent. The melting point of the acetate was from 128 to 129° and the solidifying point, 122.5°. On saponification a pure alcohol of melting point 135° was obtained.

The fruit of Limonia warneckei on analysis showed moisture, 7.26 per cent; protein, 16.26; fat, 38.5; fiber, 6.75; nitrogen-free extract, 25.72; and ash, 5.51 (0.85 per cent  $P_2O_6$ ). The following physical and chemical constants of the oil were established: Refractive index, 47.7; melting point,  $32.4^{\circ}$ ; solidifying point, from 21.5 to  $21^{\circ}$ ; acid value, 4.13; acid index, 7.34; saponification value, 188.8; iodin value, 75.2; Reichert-Meissl value, 0.55; and Polenske value, 0.55.

For the total fatty acids the following constants were obtained: Refractive index, 38.3; melting point, 44.3°; solidifying point, 38.5°; neutralization value, 199.7; average molecular weight, 280.9; and iodin value, 80.47. The free and fatty acids were found to consist largely of palmitic acid. The phytosterol

obtained by digitonin precipitation after three crystallizations showed a melting point of from 123.5 to 124°, the acetate melting at from 138 to 138.5°.

The chemistry of the volatile oil of Achillea millefolium, E. R. MILLER (Bul. Univ. Wis., No. 785 (1916), pp. 33).—In the investigation the author has obtained a blue oil from the leaves and flower heads of A. millefolium. Most of the oil is obtained from the flower heads, but very small amounts may be gotten from young plants. Drying the plant material produced no change in either the quantity or quality of oil. The oil was shown to contain l-a-pinene, d-a-pinene, l-bimonene, l-borneol, bornyl acetate and other esters of borneol, l-camphor, cineol, salicylic acid, aldehydes, formic acid, acetic acid, butyric acid (?), iso-valeric acid, at least one nonvolatile acid or lactone, and a blue constituent of high boiling point.

Note on the economic uses of rosha grass (Cymbopogon martini), R. S. Pearson (Indian Forest Rec., 5 (1916), No. 7, pp. 50, pls. 5).—This publication is divided into the following sections: Description, distribution, and mode of growth of rosha grass; method of distillation, yield, and analyses of oil; uses; production; export trade; sales of the grass and oil; and conclusions arrived at and proposals made with a view to improving the rosha-oil industry. A Note on the Constants of Indian Geranium Oil (Motia), by Puran Singh (pp. 46-50) is appended.

Saw palmetto: A phytochemical study of the fruit of Sabal serrulata, C. A. MANN (Bul. Univ. Wis., No. 767 (1915), pp. 60, pl. 1).—This bulletin reports the results of a thorough study of saw palmetto. The subject matter is considered under the heads of synonomy, natural history, the material, the chemistry of saw palmetto, moisture, inorganic constituents and ash, the so-called volatile oil, fatty oil, enzyms, carbohydrates, glucosid, alkaloid, and conclusions. A bibliography is also appended.

Muscadine grape sirup, C. Dearing (U. S. Dept. Agr., Farmers' Bul. 758 (1916), pp. 11, figs. 6).—This describes in detail the preparation of a sirup from Muscadine grapes which is considered as good as or better than other sirups usually found on the table.

The process requires only simple and inexpensive equipment which is readily available. The method consists essentially of harvesting the fruit and extracting the juice, boiling with calcium carbonate to reduce the acidity, clarifying the juice by allowing the precipitated acids to settle, boiling down the juice to a sirup of the desired thickness, usually to about one-ninth of the volume of the original clarified juice used, and canning or bottling the sirup. The varieties of grapes having the highest natural sugar and lowest acid content are recommended as making the most delicious and highest quality sirup, and also as giving the greatest yield. It is indicated that these varieties yield over 3 gal. of fresh juice per bushel of grapes and, on condensing, approximately  $1\frac{1}{3}$  qt. of sirup.

Canning without sugar, J. S. Caldwell (Washington Sta. Popular Bul. 103 (1916), pp. 4).—This bulletin briefly describes the cold-pack method and the open-kettle method, and gives some notes on canning with the use of sugar and canning in tin.

The technology of sugar, J. G. M'Intosh (London: Scott, Greenwood & Son, 1916, 3. ed., rev. and enl., pp. XV+526, figs. 244).—This is the third edition of the work previously noted (E. S. R., 15, p. 933). It is divided into the following sections: Beet sugar; cane sugar; sugar refining; and the chemistry of sugars and analysis of commercial sugars and of merchandise, etc., containing sugars.

## METEOROLOGY.

Weather forecasting in the United States (U. S. Dept. Agr., Weather Bur. Doc. 583 (1916), pp. 370, pls. 41, figs. 48).—This is a handbook or manual dedesigned especially for "the officials of the Weather Bureau for their guidance in qualifying themselves in the art of forecasting." It is the joint work of a board consisting of A. J. Henry (chairman), E. H. Bowie, H. J. Cox, and H. C. Frankenfield, appointed for the purpose, but embodies contributions from various Weather Bureau officials especially experienced in actual forecasting. The various chapters and contributors are as follows: Introductory Note-General Principles and Theories of Atmospheric Motions, by C. F. Marvin; General Circulation of the Atmosphere, by W. J. Humphreys; Weather Forecasting-Preliminary Statement, by A. J. Henry; Auxiliary Pressure-change Charts, by A. J. Henry; Lows and Highs-General Considerations, by A. J. Henry; Cold Waves, by H. J. Cox et al.; Frost Warnings, by H. J. Cox et al.; Forecasting High Winds, by E. H. Bowie et al.; Heavy Snow, Sleet, and Ice Storms, Fog, by H. C. Frankenfield, and Thunderstorms, by A. J. Henry; Weather and Temperature Forecasts, Washington District, by A. J. Henry; Forecasting the Weather and Temperature, Chicago District, by H. J. Cox; Forecasting Weather and Temperature, New Orleans, Denver, Portland (Oreg.), and San Francisco Districts, by I. M. Cline, F. H. Brandenburg, E. A. Beals, and G. H. Willson, respectively; and Long Range Weather Forecasts, by E. H. Bowie.

As regards the book as a whole the chairman of the board says: "The book will be a disappointment to those, if there be such, who have formed the expectation that it will solve the difficulties of the forecasting problem. The consensus of opinion seems to be that the only road to successful forecasting lies in the patient and consistent study of the daily weather maps. Wherein the book will be helpful, however, is in the fact that it gives the experience of those who have gone before, and it is in this sense that it will find its most useful application."

A selection of books and papers, in English, on weather forecasting by Miss Eleanor Buynitsky is included.

Principles of study of the weather, G. Lídboslavskii (Osnovania Uchenia o Pogodie. Petrograd, 1915, 2. ed., pp. VII+412, pls. 4, figs. 187).—This is a general treatise on meteorology, consisting of a revision and amplification of a series of lectures by the author at the Imperial Institute of Forestry. Following an introductory chapter on meterology in general, there are seven chapters on various phases of the statics of the atmosphere, four on the dynamics of the atmosphere, and two on weather and climate.

Tables for computing the time of moonrise and moonset, H. H. KIMBALL (U. S. Dept. Agr., Weather Bur. Doc. 580 (1916), pp. 29).—" These tables have been prepared in response to repeated demands for a simple means of determining the time of moonrise and moonset at Weather Bureau stations. They are adapted from more extensive manuscript tables, furnished by the U. S. Nautical Almanac Office, for computing the time of moonrise and moonset at any place in the United States."

Fall frosts (U. S. Dept. Agr., Nat. Weather and Crop Bul. 24 (1916), p. 3).—
"The average date of the beginning of corn harvest in the extreme northern section of the United States is between September 1 and 15, or only slightly earlier than the average date of the first killing frost. In the northern part of the so-called corn States the average date of the first fall frost is between September 25 and October 1, and in the southern part of this region about October 20. A killing frost has been recorded in most of the central and

northern parts of the country from 15 to 30 days earlier than the average date, but a thorough study of all the available data shows that the probability of a killing frost occurring earlier than 10 days before the average date is only about one in ten.

"In the northern part of the cotton region the average date of the first fall frost is between October 20 and October 25, and in the southern part of the area the average date is about one month later. A killing frost has occurred in the northern part of the area as early as October 1 and in the southern part as early as November 10. The same rule applies, however, in this section of the country as in the Northern States, that the probability of a frost occurring earlier than 10 days before the average killing date is only about one in ten."

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 3 (1916), Nos. 7, pp. 236, pls. 2, figs. 8; 8, pp. 224, pls. 2, figs. 4).—These numbers contain brief summaries and detailed tabular statements of climatological data for each State for July and August, 1916, respectively.

[The climate of Pavlovsk], A. V. SHIPCHINSKIÏ (A. SHIPCHINSKII) (Zap. Selsk. Khoz. Inst. Imp. Petra I (Mem. Inst. Agron. Emp. Pierre I), I (1916), pp. 52-69).—This is a summary of ten years' observations (1897-1904 and 1911-1913). The average annual temperature was 6.9° C. (44.4° F.); the precipitation, 500.3 mm. (19.7 in.). The prevailing wind was southeast.

## SOILS-FERTILIZERS.

The loess soils of the Nebraska portion of the transition region.—III, Potash, soda, and phosphoric acid, F. J. Alway and R. M. Isham (Soil Sci., 1 (1916), No. 4, pp. 299-316, figs. 2).—This is a third report of studies conducted at the Nebraska Experiment Station (E. S. R., 35, p. 510).

It was found that "the total potash is very uniform in distribution both from east to west and from the first to the sixth foot. While, on the whole, it is slightly lower in the eastern areas and in the higher levels, the variations are small and irregular. The proportion soluble in hot, strong hydrochloric acid seems largely dependent upon the amount of silt present, it being lowest in the most westerly area, in which, while the total potash is highest, the proportion of very fine sand also reaches its maximum.

"The total soda shows somewhat more variation. In the western four areas it is quite uniformly distributed, both from area to area and from the surface downward, amounting, in general, to a little more than half as much as the total potash. In the two eastern areas it is distinctly lower; less is found in the upper than in the lower 3 ft., and in general it amounts to a little less than half as much as the total potash. The proportion of soda soluble in strong hydrochloric acid is lower than in the case of potash and is quite uniform.

"The total phosphoric acid is still less evenly distributed. In the first 2 ft. it seems much the same from east to west, while in the two eastern areas it is higher in amount in the lower than in the upper sections. Most of it is soluble in strong hydrochloric acid, neither location nor depth seeming to influence in the proportion. . . .

"Determinations were made of the total potash, soda, and phosphoric acid, as well as of the portions of these soluble in cold 1 per cent hydrochloric acid, in four separates—clay, silt, very fine sand, and coarser particles—from typical humid and semiarid subsoils. In the very fine sand from the humid subsoil the amount of potash was found to be about the same as in the clay, but distinctly lower than in the silt. In the semiarid subsoil it was similar in the silt and very fine sand, in both of which it was only very slightly higher than

in the silt from the humid area, but was somewhat lower in the clay. In both subsoils the amount of soda was highest in the very fine sand and much the lowest in the clay. The dilute acid dissolved about four times as much potash, but only about half as much soda, from the semiarid as from the humid subsoil, but the soluble portions of both form only a small proportion of the total amounts present. On the other hand, the dilute acid removed from both more than half the total phosphoric acid, the proportion dissolved being higher in the semiarid subsoil. In the separates much more phosphoric acid was found in the clay than in the silt and the very find sand, in which it was alike.

"The most noteworthy differences were shown by treatment with citric acid solution. The potash soluble in this reagent was found to increase with the aridity; in the most humid areas it decreases from the surface downward, while in the least humid it increases, notwithstanding an accompanying increase in the carbonate content . . . In contrast with this, the citric acid-soluble phosphoric acid was found not to increase with the aridity, when [considering] the whole 6-ft. section; in the first 2 ft. it increases, but in the lower 4 ft. it decreases from east to west. In the most humid areas it increases rapidly from the surface to a depth of 6 ft., while in the most westerly areas it decreases. In the latter the difference is to be attributed to the increase in carbonate content, because when this is neutralized the sixth foot yields as much to the acid as does the first. The high content of citric acid-soluble phosphoric acid is not confined to the lower portion of the 6-ft. sections, but continues to more than twice this depth. . . . In content of potash, soda, and phosphoric acid the soils from all the areas resemble the chernozem soils of Russia and the arid soils of California."

A list of 12 references to literature bearing on the subject is appended.

The loess soils of the Nebraska portion of the transition region.—IV, Mechanical composition and inorganic constituents, F. J. Alway and C. O. Rost (Soil Sci., 1 (1916), No. 5, pp. 405-436, figs. 2).—It was found that "the loess soils of the Nebraska portion of the transition region consist chiefly of very fine sand and silt which together constitute from 77 to 95 per cent of the soil mass, the remainder being chiefly clay. From east to west the clay decreases and the relative proportions of the silt and the very fine sand change, the former decreasing and the latter increasing. The mechanical composition shows no distinct relation to the depth except that the clay content is lower in the first than in the second foot. . . .

"The samples were subjected to both a complete rock analysis and to 5-day digestion with hydrochloric acid of 1.115 specific gravity. The carbon dioxid, which is present chiefly in calcium carbonate, shows greater variations than any other constituent; while low in the first 2 ft. of all the areas, the amount in the subsoil increases markedly from east to west. The lime varies widely, both the total and the acid-soluble portion, being three times as high in the western subsoils as in the eastern. The content of magnesia shows no definite relation to that of the lime, in the eastern areas it being as high but in the western much lower; it is independent of the aridity and, except that it is lowest in the surface foot, also of the depth. The total alumina is very uniformly distributed but in all the areas shows a minimum in the surface foot. The acidsoluble portion is similar in the western four areas, but markedly higher in the eastern two; like the total it is lower in the first than in the second foot. It shows no definite relation to either the clay or the acid-soluble potash. The iron, manganese, and titanium are distinctly higher in the eastern two than in the other four areas. Almost the whole of the iron is acid-soluble; like the alumina it shows a minimum in the surface foot. The whole of the manganese is acid-soluble, but only a small part of the titanium. The silica is very uniformly distributed but, in contrast to the alumina, is in each area slightly higher in the first than in the second foot. Sulphur and baryta show no dependence upon either depth or aridity. About half of the former is acid-soluble, but none of the latter. To litmus the samples are all neutral or very slightly alkaline. The acid-insoluble matter shows no definite relation to the aridity and, except that it is higher in the first than in the second foot, none to the depth. The proportion of acid-insoluble material in the nonvolatile, carbonate-free portion of the soil is highest in the surface foot and similar in the lower levels, as though leaching had affected the silicates of only the first foot.

"In mechanical compositions these loss soils show the same characteristics as the Russian chernozem. Also, in the chemical composition of the inorganic portion, both the total and the acid-soluble, in so far as the available data permit of comparisons, there is a very marked similarity.

"A comparison with the average composition of arid and humid soils shows that, except in the proportions of manganese, the first foot samples of the loess soils from the most humid areas studied resemble the arid soils as much as do those from the distinctly semiarid western areas. In the case of this one constituent the soils from the eastern areas resemble those from the humid regions reported by Hilgard. In carbonate content the subsoils from the western and intermediate areas resemble arid subsoils and those from the eastern areas the humid soils."

A list of 15 references to literature bearing on the subject is appended.

Soil survey of Laurens County, Georgia, A. T. SWEET, G. B. JONES, E. T. MAXON, T. M. MORRISON, and E. C. HALL (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 41, fig. 1, map 1).—This survey, made in cooperation with the Georgia State College of Agriculture and issued September 12, 1916, deals with the soils of an area of 509,440 acres in the higher Coastal Plain in central Georgia.

"The topography ranges from undulating or rolling, or even broken in places in the northern part of the county and near the large streams, to almost flat in sections of the southern part. . . . The soils of the county are derived from the unconsolidated sediments of the Coastal Plain. They are prevailingly sandy in the surface portion and have sandy clay subsoils." Including swamp, 17 soil types of 13 series are mapped, of which the Norfolk sandy loam and the Grady sandy loam cover 33.4 and 11.1 per cent of the area, respectively.

Analyses of soil types of Troup County, W. A. Worsham, Jr., L. M. Carter, D. D. Long, and M. W. Lowry (Bul. Ga. State Col. Agr., No. 92 (1915), pp. 28, figs. 2).—This bulletin reports general soil survey data for the county and gives the results of chemical analyses of samples of all the types mapped, together with suggestions for utilizing the potential fertility of the soils.

Soil survey of Dekalb County, Missouri, H. H. KRUSEKOPF, R. C. DONEGHUE, and M. M. McCool (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1914, pp. 25, fig. 1, map 1).—This survey, made in cooperation with the Missouri Experiment Station and issued September 9, 1916, deals with the soils of an area of 266,880 acres in the gently rolling prairie region of northwestern Missouri, the topography of which varies from level to rolling. Regional drainage is well developed. The soils of the county are of glacial, loessial, and alluvial origin. Seven soil types of 5 series are mapped, of which the Shelby loam and the Grundy silt loam cover 54.4 and 24.9 per cent of the area, respectively.

Soil survey of Wayne County, North Carolina, B. B. DERRICK, S. O. PERKINS, and F. N. McDowell (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1915, pp. 51, fig. 1, map 1).—This survey, made in cooperation with

the North Carolina Department of Agriculture and issued August 31, 1916, deals with the soils of a fairly well-drained area of 354.560 acres in east-central North Carolina, the topography of which includes broad, gently rolling interstream areas, which become more rolling as the larger streams are approached. The county lies wholly within the Costal Plain soil province.

"The soils of Wayne County are derived from the unconsolidated sands, clays, and gravel of sedimentary origin." They include both upland and bottom land types. Including swamp, 23 soil types of 11 series are mapped, of which the Norfolk fine sandy loam, sandy loam, and sand cover 22.4, 21.4, and 13.4 per cent of the area, respectively.

Study of an exact classification of soils with reference to climate and geology, R. Lang (Internat. Mitt. Bodenk., 5 (1915), No. 4, pp. 312-346, fig. 1).— The work of others bearing on the subject is briefly reviewed, and a study of soil classification is reported in which, first, the influence of the main climatic factors in soil formation, such as temperature and humidity, and the remaining soil forming factors are dealt with. Finally, the changes produced are described by which the development of soils under special climatic conditions can take place.

It is concluded that the rain factor, computed from the average annual rainfall and the average temperature, is very important in determining the limits of the extent and conditions of the formation of a soil type.

Use of the moisture equivalent for the indirect determination of the hygroscopic coefficient, F. J. Alway and J. C. Russel (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 22, pp. 833-846).—In this contribution from the Minnesota Experiment Station, experiments with silt loam soils collected from 30 virgin prairie fields in Nebraska are reported, the purpose of which was to determine the reliability of the use of the moisture equivalent for the indirect determination of the hygroscopic coefficient in soils.

It was found that "the hygroscopic coefficient may in most cases be calculated from the moisture equivalent with sufficient accuracy to permit its use in soil-moisture studies. For certain types of soil, however, the ratio departs so widely from that assigned by Briggs and Shantz (E. S. R., 26, p. 628) that the indiscriminate use of the latter value does not seem permissible. Before employing this indirect method for the determination of the hygroscopic coefficient in connection with soil-moisture studies the ratio should be experimentally established for each of the particular types of soil involved.

"The effect of considerable quantities of organic matter is, in general, to give the ratio of the moisture equivalent to the hygroscopic coefficient a higher value. In the case of any extensive study of soil moisture involving many soil types, the same general conclusions as to the relation of the nonavailable moisture to the hygroscopic coefficient are to be expected, no matter whether the latter value be directly determined or be calculated from the moisture equivalent by the Briggs-Shantz formula. For the calculation of the moisture equivalent from the mechanical analysis no general formula appears universally applicable, the formula needing modification according to the soil type to which it is to be applied."

Soil tank investigations, S. E. Collison (Florida Sta. Rpt. 1915, pp. CII-CV).—A continuation of the investigation on the losses of fertilizing constituents in the drainage water from soil (E. S. R., 33, p. 24) is reported.

"The loss of nitrogen has increased somewhat over that for last year. The loss of potash has increased in two of the tanks and decreased slightly in the other two. . . . The loss of nitrogen was very large in the earlier periods but has decreased notably in the later ones, reaching the lowest figure in 1914, and increasing somewhat for 1915. . . . The losses of potash have increased from

the beginning to the present date with two of the tanks, while with the other two the highest point was reached in 1914. . . . The losses of lime and sulphate are still increasing."

Water table variations, causes and effects, A. B. BALLANTYNE (*Utah Sta. Bul. 144* (1916), pp. 23, figs. 16).—This bulletin reports the results of 1,111 measurements, by means of wells, of the water level variations in a soil described in a previous report by Widtsoe and Stewart (E. S. R., 29, p. 18), the purpose being to show the effect of rainfall and irrigation water at different seasons and the influence of the water level variations on soil and vegetation.

It was found that the level of the free soil water was lowered by natural drainage, surface evaporation, and growing vegetation. "The normal precipitation caused it to rise, the amount depending upon the distance of the free water from the surface and the quantity of rain falling, small amounts showing no appreciable influence." Long continued irrigations caused the water level to rise, the rise being greatest where the free soil water was nearest the surface, but apparently depending upon the length of time the stream was allowed to run on the land. "The fluctuation of the water level caused by heavy applications of water followed by long dry periods . . . caused the death of large numbers of trees and vines; the first of the former which died were those where the water was confined to two or four narrow furrows . . . made close to the trees. The ones that were alive to the last were on those parts flooded by the regular irrigations. It lessened the lucern field's production to less than one-fifth of its former normal yield. Crops of oats grown after the lucern at no time produced more than half crops. The application of less water more rapidly applied is indicated as the logical remedy for this seeped condition."

The relation between absorption and coagulation and its importance in soil, A. DE DOMINICIS (Staz. Sper. Agr. Ital., 48 (1915), No. 8, pp. 525-555; abs. in Chem. Zentbl., 1915, II, No. 26, p. 1307; Jour. Chem. Soc. [London], 110 (1916), No. 641, I, p. 240).—Experiments with clay are reported which led to the following conclusions:

The phenomena of absorption and coagulation proceed together, and a change in one is always accompanied by a simultaneous, analogous change in the other. For instance, the coagulating powers of different ions correspond with their degrees of absorption. Absorption effects a retrogression of the colloids, a diminution of the difference of electrical potential between the contrasted phases, and a rise in the surface tension, the phenomenon of coagulation thus making its appearance.

Soil colloids, P. ROHLAND (Landw. Vers. Stat., 88 (1916), No. 1-2, pp. 121-129).—A further discussion is given dealing mainly with the adsorptive powers of clay, lateritic, and red soils (E. S. R., 32, p. 318).

Bacteriological studies of a soil subjected to different systems of cropping for twenty-five years, P. L. Gainey and W. M. Gibbs (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 24, pp. 953-975, fig. 1).—Studies conducted at the Missouri Experiment Station of the bacterial numbers and ammonia and nitrate-forming powers of a silt loam soil, part of which has been in continuous culture to specific crops and part subjected to varying fertility treatment for 25 years, are reported.

It was found that the soil under continuous corn and wheat contained, in the absence of any additions of fertilizers or manure, relatively low numbers of bacteria. In the presence of manure, continuous corn and wheat soils contained relatively high numbers, manure having a much more marked effect upon numbers here than under the other crops studied. No appreciable effect upon the ability of the soil to liberate ammonia from cotton-seed meal was

obtained, but the ability to oxidize ammonia nitrogen to nitrate nitrogen was materially altered. Continuous corn and wheat with no additions of manure or chemicals brought about a relatively low oxidizing power in the soil complex. The addition of manure, and to a less extent commercial fertilizers, materially raised the oxidizing power, especially under continuous corn and wheat.

The nutrition of soil bacteria, E. R. ALLEN (Mo. Bul. Ohio Sta., 1 (1916), No. 8, pp. 249, 250).—Experiments with extracts from a fertile soil before and after the soil was ignited are reported, which show "that soil is superior to sand for the support of nitrification and that the addition of humus improves the sand while the addition of carbon black does not. Both humus and carbon black remove substances from solution by absorption, but the actions of the two... have been quite different. Ignition of soil, which would destroy its humus, helped rather than injured its power to support nitrification. The addition of humus to ignited soil exerted but little effect upon nitrification. The experiments, however, do not confirm or disprove either the physical or chemical theory."

Influence of barnyard manure and water upon the bacterial activities of the soil, J. E. Greaves and E. G. Carter (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 23, pp. 889-926, figs. 10).—Experiments conducted at the Utah Experiment Station are reported, dealing with (1) the bacterial activities of a soil receiving a definite amount of manure and measured quantities of irrigation water and kept fallow in pots under vegetation house conditions, (2) the bacterial activities in a fallow soil under field conditions receiving known quantities of manure and water, and (3) the bacterial activities of soil treated as in (2) but producing a crop. The soil used was of sedimentary nature and consisted of fine sand and coarse silt of fairly uniform physical and chemical composition to a great depth.

It was found that in a calcareous soil kept in pots for four months "the temperature of the manured and unmanured averaged practically the same for the period, but the temperature of the soil with 12.5 per cent of water averaged 1° C. higher than did soils with 22.5 per cent of water. The greatest number of organisms developed on synthetic media from the soils receiving the greatest quantity, 25 tons, of manure. There were more colonies developed from the soil receiving 12.5 per cent of water than from any of the other soils receiving higher quantities of water.

"The ammonifying powers of the soil increased with the manure applied up to 25 tons of manure per acre, but the greatest increase per ton of manure was obtained in soil receiving 5 tons. The ammonifying powers of the soils increased as the water applied increased until 20 per cent of water was applied. The ammonifying powers of soil receiving 22.5 per cent of water were not as high as were those of soil receiving 20 per cent of water. The greatest increase per unit of water applied was when the water was increased from 12.5 to 15 per cent of water.

"The nitrifying powers of the soil increased as the manure and water applied increased up to 25 tons of manure and 22.5 per cent of water.

"The nitrogen-fixing powers of the soil were greatest in those pots receiving 10 tons of manure per acre. Increasing the water above 12.5 per cent but not above 22.5 per cent slightly increased the nitrogen-fixing powers of the soil. Nothing in the results indicated that the application of manure up to 25 tons per acre and of water up to 22.5 per cent caused denitrification in the soil.

"Bacteriological analyses of fallow field soil receiving none, 5 tons, and 15 tons of manure per acre and receiving none, 5 in., 10 in., 20 in., 30 in., and 40 in. of irrigation water gave the following results:

"The maximum number of bacteria were obtained from the soil receiving 15 tons of manure. The application of irrigation water up to 20 in. increased the bacterial count, being most noticeable in the soil receiving the greatest quantity of manure. If the ammonifying powers of the unmanured soils are considered as 100 per cent and the unirrigated as 100 per cent, the manured and irrigated soils then become with 5 tons of manure, 147 per cent; with 15 tons of manure, 188 per cent; 5 in. of water, 106 per cent; 10 in. of water, 117 per cent; 20 in. of water, 108 per cent; 30 in. of water, 106 per cent; and 40 in. of water, 108 per cent. Large quantities of irrigation water produced the greatest depressing effect in the presence of 15 tons of manure per acre. The application of manure to a soil increases its nitrifying powers. The application of irrigation water to a fallow soil apparently depresses its nitrifying powers. Fewer organisms develop on synthetic agar from a cropped than from a fallow soil. The application of manure to a cropped soil increases the bacterial count of the soil. The greatest number of organisms developed from the soil receiving 10 in. of irrigation water.

"The ammonifying powers of the cropped soils were slightly lower than similarly treated fallow soils. The application of 5 and 15 tons of manure per acre to a soil increases the ammonifying powers of the soil. The application of irrigation water up to 30 in. increases the ammonifying powers of the soil. The greatest increase resulted in those soils receiving 15 tons per acre of manure. The application of 40 in. of irrigation water to corn land, especially to that receiving 15 tons of manure per acre, depresses the ammonifying powers of the soil.

"The nitrifying powers of fallow soil were higher than similarly treated cropped soils. The application of manure to a cropped soil greatly increases its nitrifying power. The application of irrigation water up to 30 in., especially to a soil receiving 15 tons of manure per acre, greatly increases its nitrifying powers.

"There was found to be a direct relationship between the bacterial count, the ammonifying powers, the nitrifying powers, and the crop produced on a soil receiving no manure, 5 tons, and 15 tons of manure per acre. A close correlation was also found to exist between the bacterial activities of soil receiving varying amounts of water and the crop produced upon the soil."

A list of 52 references to literature bearing on the subject is appended.

The value of manure as compared with chemical fertilizers, C. E. Thorne (Mo. Bul. Ohio Sta., 1 (1916), No. 8, pp. 253, 254).—A review of experimental work at the staton shows that "open-yard manure of good quality should not cost more than about \$2 a ton and manure fresh from the stable not more than \$2.50 a ton, spread on the field, as compared with nitrate of soda at \$60 a ton, 16 per cent acid phosphate at \$18, and muriate of potash at \$50 properly compounded and spread on the field." On the other hand it is pointed out that 100 tons of manure produced annually from well-fed animals and used in a systematic rotation of crops and supplemented with acid phosphate, bone meal, or raw rock phosphate may be expected to produce as large an increase in crops as an annual expenditure of \$200 to \$250 in chemical fertilizers.

The decomposition of the organic matter of kelp in the soil, A. W. CHRISTIE (Jour. Indus. and Engin. Chem., 8 (1918), No. 5, pp. 425-427; abs. in Chem. Abs., 10 (1916), No. 11, p. 1571).—Experiments conducted at the California Experiment Station on the extent and rate of decomposition of kelp in fine sandy loam soil as compared with manure, straw, and alfalfa are reported. The two samples of kelp used were Macrocystis pyrifera and Nereocystis leutkeana. It was found that "dried and ground kelp decomposes in the soil under laboratory

conditions, increasing the humus content to an extent comparable with alfalfa, manure, and straw. Of the pentosans present, 75 to 80 per cent was decomposed in all the materials."

The solvent action of ammonium salts on phosphorites in sand cultures, F. V. Chirikov (T. Tschirikuw) (*Iz Rezul't. Veget. Opytov. Lab. Rabot (Rec. Trav. Lab. Agron.*), 9 (1913), pp. 436-440).—This is a continuation of the experiments with sand cultures conducted in 1912 (E. S. R., 29, p. 624). In addition to calcium carbonate, magnesium carbonate was also used in 1913 to secure neutralization of ammonium salts, both being taken in quantities equivalent to one-half or all of the sulphuric acid in ammonium sulphate. The phosphorite was Russian, containing 25.86 per cent of phosphoric acid.

The results of the experiments with barley were fully concordant with those obtained the previous year. No decrease in the yield resulted from neutralization of the acid with calcium carbonate, but the yield declined when magnesium carbonate was used in place of calcium carbonate. In the experiments with buckwheat the yields were lower when calcium nitrate was replaced by ammonium sulphate.

Relation of calcium carbonate to the soil phosphates and acid phosphate, J. L. Burgess (Bul. N. C. Dept. Agr., 37 (1916), No. 5, pp. 16).—This is a brief popular discussion of the subject based largely on work at the different state experiment stations.

The influence of lime on the yield and nitrogen content of corn, A. W. Blair and H. C. McLean (Soil Sci., 1 (1916), No. 5, pp. 489-504, figs. 3).—In experiments at the New Jersey Experiment Station on a medium loam soil with a series of 20 twentieth-acre plats arranged for a study of nitrogen availability, an application of ground limestone at the rate of 2 tons per acre increased the yield of shelled corn by about 10 bu. and of stover by 432 lbs. per acre, as compared with the yield from a similar series of unlimed plants.

"The influence of the lime on the yield from the plat which annually received its nitrogen in the form of ammonium sulphate, as compared with the yield from the similarly treated plat, unlimed, was especially marked. liming likewise resulted in greatly increased yields on certain of the plats which received their nitrogen in the form of rather slowly available organic materials, as, for example, wheat or rye straw. It also resulted in decided increases in the yields on plats which received minerals only, indicating that in the soil of these plats there was a considerable store of inert nitrogenous material which required only a favorable soil reaction to make it available. Unlimed plats which received an extra heavy application of manure, or manure and nitrate of soda, gave yields fairly approaching or even surpassing the yields given by plats which received similar nitrogenous treatment and lime. That is, the manure or the basic materials in the manure and nitrate of soda apparently decreased the need for lime. The average percentage of nitrogen in the grain and stover from the limed plats was slightly greater than the average in the grain and stover from the unlimed plats. The average recovery of nitrogen from the limed plats was 36.2 per cent and the average from the unlimed plats was 25 per cent."

A list of 18 references to literature bearing on the subject is appended.

Effect on plant growth of sodium salts in the soil, F. B. HEADLEY, E. W. Curtis, and C. S. Scofield (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 22, pp. 857-869, figs. 8).—Pot experiments with wheat on sandy loam, loam, and beach sand to determine the influence of the carbonate, bicarbonate, chlorid, and sulphate of sodium when added in amounts varying from nothing to sufficient to prevent plant growth entirely are reported.

It was found that "only a part of the salt added to the soil in pot cultures could later be recovered from it by water digestion. This apparent loss of salt . . . was greater in the case of sodium carbonate and sodium sulphate than with sodium chlorid.

"Where sodium carbonate was added to a soil the absorption was greater in fine soil, rich in organic matter, than in sand. The limit of tolerance of crop plants to the salt in the soil is determined by the quantity of salt that can be recovered from the soil rather than by the quantity added to the soil. The carbonates and bicarbonates of sodium are mutually interchangeable in the soil, and the toxicity of the soil solution appears to depend upon the quantity of the basic radical held in the soil regardless of the form of the acid radical... The proportion of recoverable salt which would reduce by one-half the growth of wheat seedlings was for the carbonates 0.04 per cent of the dry weight of the soil, for the chlorids 0.16 per cent, and for the sulphates 0.35 per cent. The proportion of recoverable salt which prevented germination of wheat was for the carbonates 0.13 per cent, for the chlorids 0.52 per cent, and for the sulphates 0.56 per cent."

The toxic action of soluble aluminum salts upon the growth of the rice plant, K. Miyake (Jour. Biol. Chem., 25 (1916), No. 1, pp. 23-28; abs. in Jour. Soc. Chem. Indus., 35 (1916), No. 12, p. 700; Chem. Abs., 10 (1916), No. 14, p. 1902).—Experiments conducted at the University of California are reported in which rice seedlings were grown in solutions of aluminum chlorid and hydrochloric acid of concentrations varying from 1/1,000 normal to 1/20,000 normal.

It was found that aluminum chlorid was toxic to the growth of rice seedlings, even in dilute solution, the toxic effect appearing in concentrations greater than 1/7,500 normal. "The toxicity of aluminum chlorid seems to be approximately equal to that of hydrochloric acid of the same normality, [and] is not due to the hydrogen ion formed by hydrolysis of the salt in solution. The concentration of hydrogen ions formed by the hydrolysis of aluminum chlorid is less than that formed by dissociation of hydrochloric acid of the same normality. Since the chlorin ion is not toxic to the growth of rice seedlings in such dilute solution, colloidal aluminum hydroxid or unhydrolyzed aluminum chlorid molecules or aluminum ions may be the toxic factors. The toxicity of soluble aluminum salts is dependent upon the amount of aluminum itself,

"The determination of soil acidity by titration in which the soil extract is titrated with standard alkali is a logical method of determining the amount of bases which should be added to the soil for the amelioration of its infertility; because, although the titration does not indicate the true acidity of the soil, yet it does afford a measure of the bases which must be added to neutralize the free acid and decompose the aluminum salts, either or both of which may be responsible for the infertility."

The agricultural value of greensand marl, A. W. Blair (New Jersey Stas. Circ. 61 (1916), pp. 2-13, fig. 1).—This circular includes a discussion of the agricultural value of greensand marl, and reports analyses of 42 samples collected in New Jersey showing that the phosphoric-acid content varied between 0.045 per cent and 2.31 per cent and the potash content between 1.03 per cent and 6.5 per cent.

The utilization of molasses as a manure, L. DE WAAL (*Internat. Sugar Jour.*, 18 (1916), No. 210, pp. 267-272).—Fertilizer experiments with molasses in heavy clay and sandy cane soils are briefly reported.

The results are taken to indicate that "molasses constitutes a valuable rectifier for cane soils, which, when applied in combination with organic matter, has given marked results in estate experiments on a large scale during three consecutive years. Even in a diluted form the results were very encouraging.

# AGRICULTURAL BOTANY.

Hybrids of the genus Epilobium, R. Holden (Amer. Nat., 50 (1916), No. 592, pp. 243-247, figs. 4).—The author has extended the investigations of Jeffrey (E. S. R., 31, p. 823; 32, p. 521) on the relation of hybrid infertility to defective or abnormal development of the gametic elements. He now reports on some observations of two sections of the genus Epilobium, Chamænerion and Epilobium proper, the latter having typically regular flowers and spores persistent as tetrads, the former habitually showing considerable irregularity and even absence of protoplasm in some of the spores, a condition supposed to indicate impurity.

Investigation of North American forms agreed with the expectation as above noted, but English specimens showed abortive spores not only in *E. montanum*, *E. parviflorum*, and *E. hirsutum*, but also in *E. angustifolium*. This fact, at first apparently contrary to previous observations, appeared on further investigation to be due to the presence of two varieties of *E. angustifolium* in England, *E. macrocarpum* and *E. brachycarpum*, and to the fact that wherever these are found growing together cases of partially abortive spores are also found, indicating a hybrid origin of such plants. This state of affairs is said to exist not only in England but probably also in Europe, Asia, and western North America, where both varieties are known to coexist; while the spores are all normal in localities where but one variety exists. Chamænerion is therefore regarded as affording confirmation instead of refutation of the value of abortive pollen grains as a test of hybridization.

The genetic behavior of the hybrid Primula kewensis and its allies, Caroline Pellew and Florence M. Durham (Jour. Genetics, 5 (1916), No. 3, pp. 159-182, pls. 7).—The authors have made a progress report on their study of the genetic behavior of P. kewensis (known to have originated in 1900 as a hybrid between P. floribunda and P. verticillata), its parents, numerous derivatives, and genetic combinations. The experiments consisted in breeding the various forms in large numbers and in making all cross-fertilizations possible among them. The results are given in considerable detail.

It is stated that from the cross *P. verticillata* by *P. floribunda* and the reciprocal, and, in fact, between any two forms, plants representing the female parent are usually obtained. The suggestion is considered as evident that this is a case of actual parthenogenesis or else of monolepsis (in which ovule development requires the stimulus of fertilization, but in which, however, the pollen grain really makes no genetic contribution to the final product). These maternal hybrids rarely show evidence of segregation when used for crossing and usually breed true to type on self-fertilization. It is stated that under most stringent tests positive evidence of true parthenogenesis has been obtained, but the evidence as a whole favors the theory that while the ovules can develop without fertilization they more commonly develop in consequence of that stimulus.

The offspring of the tetraploid *P. kewensis*, both on selfing and crossing, generally reproduced the female type simply, but a single diploid individual has been produced from this form. This has exhibited segregation of an almost normal kind and has given new forms representing combinations of *P. floribunda* and *P. verticillata*, the seeds of which generally germinate freely in contrast with those commonly obtained from *P. kewensis*. Among these new forms are many shades of yellow not previously known in these plants. The factorial relations are still under investigation. The diploid plant has been crossed with the tetraploid *P. kewensis*, the results being plants intermediate between *P. floribunda* and *P. kewensis* and a few resembling *P. floribunda*.

Mendelian inheritance in varietal crosses of Bryonia dioica, W. N. Jones and M. C. Rayner (*Jour. Genetics*, 5 (1916), No. 3, pp. 203-224, pls. 3, figs. 6).—Results of breeding experiments on the genetical behavior of certain differentiating features in two strains or varieties of B. dioica are reported.

The author states that the absence of a waxy bloom on the ripe berries of one variety behaves as a simple dominant to the presence of a waxy bloom on the berries of the other variety, the presence and absence of bloom behaving as a pair of simple allelomorphic factors. The observed proportion of two-carpellary to three-carpellary flowers obtained by crossing the two varieties can be interpreted by assuming the cooperation of two factors. The numbers of vascular bundles in the stems of these two varieties are typically 10 (5+5) and 14 (7+7) respectively, the capacity to increase the number of bundles beyond 10 behaving as a simple dominant to absence of such capacity. Differences relating to habit and foliage are evidently complex in origin, requiring further study. It is regarded as determined that crossing leads to the production of new types in the second generation, that segregation occurs involving the reappearance of the original characters of the grandparents in the  $F_2$  generation, and that the number of factors for leaf shape is probably not over two.

The experiments on Bryonia emphasize the need for caution in the subdivision of existing species without regard to breeding tests. It is thought that a number of segregates showing morphological differences due to new combinations can arise from the intercrossing of a few stable types within the limits of a so-called species. The stability of these new forms can be tested only by breeding, and the extreme types among them may be connected by an almost continuous series of transition forms.

Studies on size inheritance in Nicotiana, E. M. East (Genetics, 1 (1916), No. 2, pp. 164-176, figs. 4).—The results of a study of simple and obvious Mendelian phenomena, as noted in a cross between two varieties of N. longiflora, are reported.

The author states that the minimum number (not less than eight) of requirements, mostly independent mathematically, which should be met by pedigree culture data when all populations succeeding the original cross are obtained by self-fertilization, are met by data here presented or elsewhere observed, and that not one fact has been discovered to be directly opposed to them. Considering these data apart from other known facts, it is held that while the evidence tends to justify the use of the plural segregating factors in the interpretation of size inheritance, dogmatic conclusions should not be drawn from a single set of experiments. Numerous size studies by authors mentioned should be considered together in order to arrive at a reasonable judgment as to the mechanism by which such characters are transmitted.

Some notes on the Linaceæ. The cross pollination of flax, J. V. Eyre and G. Smith (Jour. Genetics, 5 (1916), No. 3, pp. 189–197).—It is stated that while testing many species of Linaceæ for cyanophoric glucosids during the past three years, it was noted that those species having white, red, or blue flowers were more or less richly cyanophoric, whereas the yellow-flowered species, which usually show a different habit, failed to yield hydrogen cyanid and appeared to lack cyanogenetic enzym. Studies made during 1913 on a large number of both blue and yellow flowered species have confirmed observations previously reported (E. S. R., 28, p. 503).

In view of an expected early interruption of this study, a provisional report is made on the details of recent progress in work, which is still incomplete.

Note on experiments with flax at the John Innes Horticultural Institution, W. BATESON (Jour. Genetics, 5 (1916), No. 3, pp. 199-201).—The author reports

failure in attempts to cross the annual homostyled *Linum usitatissimum* with some such heterostyled species as *L. perenne*. He states, as a result of experimentation briefly noted, that the raising of a tall strain of flax is a very easy matter and can be done by selection of materials already existing in common crops. It is thought that most seed produced under natural conditions results from self-fertilization.

It is thought by the author that besides the oil flaxes, which are about 1.75 ft. in height, there are in England pure types of at least three other heights, the native tall strain measuring about 4 ft., several ordinary blue, and also some white, forms about 3 ft. high, and a dark blue true-breeding type about 2.5 ft. in height.

The ecological histology of prairie plants, Ella Shimek (*Proc. Iowa Acad. Sci., 22 (1915), pp. 121–126, pl. 1*).—The material for this investigation, which is here only partially reported but which is intended to ascertain the character of the various structural adaptations to environment made by ordinary plants in Iowa, includes 65 of the 271 species characteristic of the prairies. It is stated that the flora of the prairie is essentially xerophytic, differing from desert flora chiefly in the degree of modification for protective purposes. The xerophytic adaptations vary in different species as do the xerophytes of the desert, though usually in smaller degree.

On the behavior of an excised branch of the Sahuaro, R. J. Pool (*Plant World*, 19 (1916), No. 1, pp. 17-22, fig. 1).—A branch of the giant cactus (*Carnegica gigantea*), having been removed from Tucson, Ariz., to Lincoln, Nebr., produced several flowers in 1914 and a much greater number in 1915, but no fruits were produced from any of these flowers. A second specimen treated in like manner produced neither flowers nor fruits in 1915.

On the association and possible identity of root-forming and geotropic substances or hormones in Bryophyllum calycinum, J. Loeb (Science, n. ser., 44 (1916), No. 1128, pp. 210, 211).—An account is given of recent experiments which led the author to conclude that the substances responsible for root formation in the stem of B. calycinum are associated or possibly identical with the substances causing geotropic curvatures of the stem of this plant. This close association or identity of organ-forming and geotropic substances, it is thought, might also explain the regeneration that takes place in certain coniferous trees when the uppermost horizontal branch begins to grow vertically if the apex is cut off.

Do fungi live and produce mycelium in the soil? S. A. Waksman (Science, n. ser., 44 (1916), No. 1131, pp. 320-322).—By a method of incubation for a comparatively short period, the author has found evidence indicating that a number of organisms form mycelium in the soil. About 15 species were found more or less commonly in soils of different types and from different localities, Mucor circinelloides, Zygorhynchus vuilleminii, a green Trichoderma, Rhizopus nigricans, and M. racemosus being found most abundantly. The Zygorhynchus was the only organism isolated at depths of from 12 to 30 in. A number of other organisms were only rarely found, which are quite usually found present by the dilution method of plating. Organisms such as species of Aspergillus, Alternaria, Cladosporium, and most species of Penicillium did not appear on the plates within 24 hours when the soil had been inoculated directly upon sterile medium.

The red color of the mesocarp of seeded fruits in the persimmon (Diospyros kaki). A visual method for estimating astringency, F. E. LLOYD (*Plant World*, 19 (1916), No. 4, pp. 106-113, ftg. 1).—It is stated by the author that in persimmons of the race Zengi, studied by him, the region of nonastringency is not coextensive with that of the red colored tissues. From this it is inferred

that the red coloration is a consequence of the changes leading to nonastringency and is itself not the cause of that condition.

A visual method for accurately measuring astringency is given. It is based on the observation that the degree of astringency depends on the degree of adsorption of tannin by the X-cellulose (a carbohydrate of the nature of cellulose).

The theories of photosynthesis in the light of some new facts, H. A. Spoehr (*Plant World*, 19 (1916), No. 1, pp. 1-16).—Following a review of the studies which have been concerned chiefly with the reduction of carbon dioxid to formaldyhyde, the detection of formaldehyde in illuminated green plants, and the experimental employment of formaldehyde as the sole source of carbon for plants, the author gives an account of experiments carried out by himself at Tucson, Ariz., where the days are largely clear and the light intense, a great number of experiments having been made with the object of reducing carbon dioxid by means of light from various sources.

It was found that neither when mixed with water vapor nor when dissolved in water did carbon dioxid, though exposed from 1 to 150 hours, ever yield conclusive tests for the presence of formaldehyde. Formic acid was the only reduction product obtained, which fact is considered as important. The author states that his studies on the action of gaseous formic acid on green plants in the light show that, although this compound is toxic to the roots, the chlorophyllous portions develop normally in an atmosphere of formic acid, show an appreciable gain in dry weight, and form starch.

It is stated that, although the same criteria which have been applied to the formaldehyde theory may be urged perhaps even more consistently in favor of a formic acid hypothesis, this fact still does not appear to the author to justify the formulation of a formic acid hypothesis.

A simple and rapid method of studying respiration by the detection of exceedingly minute quantities of carbon dioxid, A. R. HAAS (Science, n. ser., 44 (1916), No. 1125, pp. 105-108).—A description is given of a simple apparatus that may be used in determining the respiration of organisms, the amount of respiration being accurately observed by changes in the colors of indicators added to solutions which contain the organisms.

It is found that exceedingly small amounts of carbon dioxid may be determined with great accuracy. As changes in color often occur within a few minutes, it is claimed that the experiments may be so shortened as to exclude pathological changes in the organisms. As the amount of carbon dioxid can be determined without disturbing the organisms, a study of the dynamics of the method is made possible.

The controlling influence of carbon dioxid.—III, The retarding effect of carbon dioxid on respiration, F. Kidd (Proc. Roy. Soc. [London], Ser. B, 89 (1916), No. B 612, pp. 136-156, figs. 3).—Previous work (E. S. R., 32, p. 328) has led to the conclusion, among others, that the resting condition of moist seed often observable in nature is primarily a phase of autonarcosis under the influence of carbon dioxid produced by the seed itself (retardation and suspension of normal activity in plant protoplasm being produced by carbon dioxid in conditions otherwise favorable to growth and during a stage normally characterized by vigorous growth). The author has now extended these investigations to plant tissues in general in order to determine the mechanism of such narcosis. The influence of carbon dioxid upon respiration has been studied on account of its apparent connection with growth by cell division.

It has been found that carbon dioxid in plant tissues causes a depression of anaerobic carbon dioxid production. This depression is not due to permanent disorganization, as it is temporary and disappears with the disappearance

of its cause. It occurs under both anaerobic and aerobic conditions. Depression of aerobic respiration is shown when measured by either oxygen consumption or carbon dioxid production. Where oxygen is so scant that some carbon dioxid is produced anaerobically, carbon dioxid has no retarding effect on oxidation. A quantitative relation exists between carbon dioxid concentration and the depression of aeroble respiration as in anaerobic carbon dioxid production. It is held that of the two types of respiration demonstrated by Blackman and others (E. S. R., 26, p. 822), namely, floating respiration and protoplasmic respiration, it is the former only which is depressed by the retarding action of carbon dioxid.

The main conclusion to be drawn from these results as regards the inhibitory action of carbon dioxid upon growth is that a marked reduction of respiration is involved in the mechanism of carbon dioxid narcosis. It is considered that anaerobic and aerobic carbon dioxid production are processes genetically connected in normal respiration, and that the rate of the anaerobic process acts as the limiting factor in normal respiration.

Osmotic pressures in plants.—VI, On the composition of the sap in the conducting tracts of trees at different levels and at different seasons of the year, H. H. DIXON and W. R. G. ATKINS (Sci. Proc. Roy. Dublin Soc., n. ser., 15 (1916), No. 6, pp. 51-62, fig. 1).—In a previous publication (E. S. R., 35, p. 26), the authors showed that sap centrifuged from the wood of trees always contained sugars and salts, the former predominating as a rule. In the present paper, an account is given of a study on the composition of the sap at different levels in the same tree and at different seasons of the year upon closely similar trees. Nine trees were used in the experiments, including 4 deciduous trees, 3 evergreens, and 2 sub-evergreens.

It was found that large quantities of sap may be centrifuged from the conducting wood of trees, and that the sap varies in color and in electrolyte and nonelectrolyte content. When in a condition of physiological rest during the late autumn and winter, the osmotic pressure of the wood sap of deciduous trees is small and practically constant. During the early spring the sap is enriched by the addition of large quantities of sugars from the storage cells of the wood parenchyma and the medullary rays, and the osmotic pressure rises in a very marked degree from root to summit. During the late spring, the concentration of sugars is still considerable, being roughly half of the earlier value. The electrolytes of the sap are, however, present in much greater concentration than in the early spring.

In *Acer macrophyllum*, reducing sugars are never found in the wood sap except in traces, while sucrose is present in quantity. In the other trees examined, both reducing sugars and sucrose were present, the latter predominating as a rule. During the vernal mobilization of reserves, the reducing sugars consist of hexoses and maltose. At other times, the latter is absent.

In evergreens and sub-evergreens the seasonal changes are not very striking nor are the gradients of osmotic pressures from root to summit so regular as in deciduous trees. The osmotic pressure of the transpiration sap in the root exceeds that in the stem at certain seasons.

Imbibitional swelling of plants and colloidal mixtures, D. T. MacDougal (Science, n. ser., 44 (1916), No. 1136, pp. 502-505).—Attention is called to the fact that the swelling of gelatin in distilled water, alkali, and acid has been used as a reference phenomenon in interpreting the water relations of plants, especially in growth. During the course of the studies of growth (which is considered to be largely dependent upon absorption and retention of water), disks of the flattened joints of an Opuntia were cut and so arranged as to show variations in swelling. It was found that both young and old tissues take up more

water when neutral or alkaline, and acidity, in addition to retarding enzymatic action presumably including respiration, operates to decrease imbibition by plant tissues.

Having found that plant cells show the greatest capacity for imbibition of water, not in acidified, but in alkaline solutions, the author has attempted to find substances or mixtures of substances that behave in a like manner. The effect of increasing percentages of agar in a gelatin mixture has been investigated, from which it appears that the mixture swells more in distilled water and less in acid or alkali. Concerning the relative effects of acid and alkali, definite conclusions have not been reached, but the data suggest that acid tends to increase imbibition at the ends of the series, while alkali tends to increase it in the mixtures containing the two colloids in more nearly equal proportions.

The penetration of balanced solutions and the theory of antagonism, W. J. V. OSTERHOUT (Science, n. ser., 44 (1916), No. 1133, pp. 395, 396).—It is stated that antagonism has been explained by assuming that antagonistic substances prevent each other from entering the cell. A difficulty is said to be found in the fact that they slowly penetrate the cell even in a properly balanced solution. This difficulty, however, disappears if it is supposed that the antagonistic substances affect certain life processes which control permeability. So long as they are present in the right proportions their effect on these processes is favorable and their penetration into the cell can do no harm. The preservation of normal permeability is regarded as the result rather than the cause of antagonism.

Antagonism and Weber's law, W. J. V. OSTERHOUT (Science, n. ser., 44 (1916), No. 1131, pp. 318-320).—The fact that Weber's law governs antagonism is explained by a dynamical theory formulated by the author. This theory assumes that injury and death result from processes which are inhibited by salt compounds formed by the union of salts with protoplasm. If these compounds are formed in a surface, the amounts will, above a certain limit, be independent of variations in concentration and will depend only on the proportions of the antagonistic salts.

#### FIELD CROPS.

Transpiration as a factor in crop production, T. A. Kiesselbach (Nebraska Sta. Research Bul. 6 (1916), pp. 3-214, figs. 48).—Part 1 of this bulletin is devoted to a discussion of work by earlier investigators in measuring the water loss through plants, the methods employed in the present study, and the factors influencing the results; part 2 to the description of the experiments and the presentation of the data secured; and part 3 to the application of the results in farm practice. The investigations were conducted to determine principles underlying the use of water by crops, and for this purpose plants were grown to the maturity at which they are usually harvested and under controlled conditions in pots, generally 16 by 36 in. in size, having a capacity of approximately 250 lbs. of moisture-free soil and sufficiently large to produce a normal plant. Means taken for the elimination of errors are discussed and 88 references to the literature cited are given.

Corn was grown to study the relation of environmental factors to the water requirement. Sunflowers and several sorghums were compared with corn, and a number of varieties differing in acclimatization and plant characters were compared with each other. The rain was excluded from the pots and evaporation from the soil surface was reduced to an almost negligible amount. Nearly all pots were situated in a corn field with their top level with the surrounding land, and the plants produced normal yields.

The rate of water loss from a corn plant was found to be affected in a rather similar manner by changing climatic conditions as it was from a physical free water surface. The amount of water transpired from a given area of leaf expanse was determined as approximately one-third as great as the evaporation from a free water surface of the same area. The rates of transpiration and evaporation, following the same general sequence as the diurnal climatic factors, increased gradually from early morning, reached the maximum between 1 and 3 p. m., and gradually receded until late in the evening. Transpiration was reduced relatively more than evaporation during the night, suggested as due to the almost complete closing at night of the leaf stomata.

The daily variation in the water requirement was found to be very marked, the maximum observed in two successive days being 600 per cent. The data further showed that under extreme atmospheric conditions as high as 10 lbs. of water may be transpired by a single corn plant during 24 hours. Such days, it is pointed out, are very critical for corn when the soil moisture is insufficient to meet this demand. The weekly amount of water used gradually increased up to the development of the maximum leaf area, and for four or five weeks after this time the transpiration rate remained high, fully one-half of the total water used by the plant being transpired during this period. While a marked variation in the water requirement of different years was observed, there existed a rather consistent relationship in the relative seasonal variations between the transpiration per unit of dry matter, the transpiration per unit of leaf area, and the evaporation from a free water surface. As an average for three greenhouse tests conducted during two years a difference of 22 per cent in relative humidity and 1.7° F. during the day caused a difference of 42 per cent in the water requirement per pound of dry matter, 38 per cent in the transpiration from a unit of leaf area, and 46 per cent in the evaporation from a free water surface. Corn plants in greenhouses transferred from a humid atmosphere to a dry one and vice versa exhibited no difference in transpiration rate under the changed conditions as compared with each other.

A transpiring leaf was found to be uniformly cooler than a dead, dry one, amounting under extreme conditions to 8.6° in the sun and 4.2° in the shade at 2 p. m., when transpiration was maximum. The transpiring leaf as compared with the air at that time was 4.1° cooler in the sun and 3.2° cooler in the shade. Other data secured showed that vegetation is a great protection against excessive transpiration and also against evaporation from the soil surface.

A reduction in soil moisture content below the optimum during three years reduced the water requirement per pound of ear corn 4.3 per cent and per pound of total dry matter 7.9 per cent, but it also reduced the stalk yield by 37.3 per cent, the yield of ear corn by 28.5 per cent, and the yield of total dry matter by 30.7 per cent. An increase in the soil moisture content above the optimum during three years increased the water requirement per pound of ear corn 13.5 per cent and per pound of total dry matter 8.2 per cent, being accompanied by a reduction in stalk yield of 11.3 per cent, yield of ear corn of 21.1 per cent, and yield of total dry matter of 16.7 per cent.

The water requirement per pound of dry matter was found to be much larger in an infertile than a fertile soil. As an average for two years, equal applications of sheep manure to infertile, intermediate, and fertile soils reduced the water requirement for ear-corn production 42.6, 25.4, and 10.5 per cent, respectively; for total dry matter the reduction was 28.9, 17.1, and 8.1 per cent, respectively. On the other hand, the total water requirement per plant was increased, respectively, 106.7, 42.6, and 28.7 per cent. The reduction in water requirement per pound of dry matter is regarded as being more a matter of plant nutrition than of transpiration.

Varieties of corn grown continuously for many years under humid and under relatively dry conditions were found to have approximately the same average water requirement per pound of dry matter. The extreme variation in the water requirement of 11 varieties of corn differing in acclimatization and habits of growth was 230 lbs. and 296 lbs. per pound of dry matter, although most varieties were rather uniform in this regard. Several varieties with alleged special drought resistance possessed practically the same water requirements per pound of dry matter as the average of all the 11 varieties tested. The water requirement for milo maize was the same as the average for the 11 varieties, but for Black Amber sorghum it was considerably higher. Wild sunflowers exhibited a water requirement per pound of dry matter approximately double that of corn and a total water use somewhat greater than that of three corn plants.

In a study of the intake of soil solutes data were obtained concerning the relation between transpiration and ash content as affected by atmospheric humidity, seasonal climatic differences, soil fertility, soil moisture, kind of crop and variety, and limitation of the amount of soil through the size of the potom-An increase in the greenhouse in atmospheric humidity, lowering the free water evaporation 47 per cent, reduced the amount of water transpired per gram of ash content 38 per cent and per gram of dry matter 40.5 per cent. A natural climatic difference, lowering the free water evaporation 40 per cent during July and August in 1913 as compared with 1914, reduced the transpiration per gram of ash content 22 per cent and per gram of dry matter 27 per cent. Under otherwise equal conditions the amount of water used per unit of dry matter fell, and the amount of solute taken in per unit of water transpired, as well as the amount taken into the plant, the dry matter produced, and the total amount of water transpired, rose with the availability of the soil solutes in different degrees of soil fertility. As compared with an abundance of moisture, less water was transpired per gram of ash content and also per gram of dry matter in a relatively low soil saturation. The influence of the size of the potometer was brought out by the fact that in potometers containing 32.5, 85, 150, 239, 583, and 956 lbs. of soil the amount of transpiration per gram of ash content was 6.14, 5.7, 5.2, 5.5, 5.07, and 4.32 kg., respectively. From a review of all the data the author believes it may be concluded that at least within the practical limits of crop production, other things being equal, an increase in the density of the soil solution is accompanied by an increase in the amount of solute taken into the plant per unit of water transpired.

Considerable variation was determined between the different varieties of corn and sorghum with reference to the thickness of the leaf and of the epidermis, and also in the number of stomata per unit of leaf area, but without an apparent striking or consistent correlation with the transpiration rate per unit of dry matter or per unit of leaf area of the different varieties, and also without striking response in the relative number of stomata to variation in either soil moisture or soil fertility. As an average for 11 varieties of corn, a plant having 949 sq. in. of leaf area had 104,057,850 leaf stomata, which occupied in the epidermis of both sides of the leaf, when open, 1.52 per cent of the area of the leaves. The entire epidermis comprised 30.8 per cent of the leaf thickness.

"Transpiration appears to be a purely physical phenomenon, depending primarily upon the moisture supply in the leaf and the evaporating power of the atmosphere, which is modified in some degree by temperature effects resultant within the leaf from chemical activity, transpiration, and from the absorption of radiant energy."

[Report on the progress of farm crops investigations] (Missouri Sta. Bul. 141 (1916), pp. 29-31, 36-39, fig. 1).—In wheat breeding investigations con-

ducted in 1914 by C. B. Hutchison and E. M. McDonald, 49 of 112 pure lines of wheat selected from 12 commercial varieties gave larger yields than the variety from which they were selected. Of 34 pure lines of Mediterranean 16 yielded 33.7 and 18, 23.5 bu. per acre as compared with 28.68 bu. for the commercial variety. In another test of 62 selections from hybrids compared with their parents and with pure lines selected from these parents, the pure lines in most cases gave the better yields.

Selections were also made of winter oats and winter wheat in connection with work carried on by C. B. Hutchison, E. M. McDonald, and A. R. Evans. Winter Turf and Culbertson winter oats came through the winter of 1913–14 in good condition, while Argentine Winter and Texas Red Rust Proof badly winter-killed. The varieties of winter barley under experiment were Tennessee Winter, Wisconsin Winter, Tenkan, and two-row Hybrid.

Studies of the adaptation of the important types, varieties, and regional strains of alfalfa to Missouri conditions and cultural experiments with soy beans were pursued by J. C. Hackleman. In 1914, when a severe drought reduced the yield of alfalfa, the largest total yield, 2.25 tons per acre, was secured from seed which came from Mongolia, and the next best yield was secured from seed of Minnesota Grimm. Good yields were also obtained from seed from France, Montana, and Bohemia. The yields from tests of different rates of seeding of soy beans were placed from best to poorest at 42, 104, 64, and 82 lbs. per acre. In trials with placing the rows different distances apart the largest yield of hay was secured with the distance of 40 in. between the rows, followed by rows seeded 8, 24, 16, and 32 in. apart, in the order named.

Sweet clover investigations were conducted by C. B. Hutchison, J. C. Hackleman, and A. R. Evans. A dry season interfered with the work. A wide variation in the percentage of hard seed in the samples sown was observed. Many samples germinated as low as 10 per cent, while sulphuric acid treatment increased the germination to as much as 60 per cent in some cases. The best stands were obtained by seeding alone between April 1 and June 1 and between August 15 and September 1.

A study of spring, summer, and fall grown crops for forage was made by J. C. Hackleman and A. R. Evans. The best combinations of fall-sown crops for winter pasture and spring forage were rye and vetch and rye and crimson clover. In the spring-sown series rape proved the best forage crop, both in growth and in drought resistance. In a summer-sown series harvested in October very little difference in weight of dry forage between sorghum and cowpeas and corn was observed. There was a larger percentage of peas in the corn than in the sorghum, although the seeding of peas was at the same rate. The difference in yield was less than 5 per cent of the total in favor of the cowpea mixture.

Observations on the relation of cowpea growing to wheat production on continuously cropped land, made by C. A. LeClair, indicated that where wheat is grown continuously and cowpeas are planted after each crop a better yield of wheat is obtained than if the soil is fallowed.

In experiments with corn and cowpeas, conducted by M. F. Miller and C. A. LeClair, the results of two years' work showed that if corn and cowpeas are seeded together at the same time the growth of both plants is limited. A decrease in the percentage of nitrogen in the ear of corn resulted when cowpeas were planted in the row with corn, while where the cowpeas were drilled between the rows at the last cultivation a slight increase in the nitrogen content of the ear resulted. For the two years there was also an increase in yield of 3 bu. to the acre, and an increase in the amount of stover in proportion to that of the grain.

A study of factors influencing the development of the maize plant, made by M. F. Miller and J. C. Hackleman, indicated that with reference to both moisture and nutrition the second period, from the time when the corn is normally laid by until the silks appear, is the most important in the growth of the plant. It was found that leaf growth was influenced more than stalk growth by the variation in the nutrient elements. With reference to variation in the moisture supply, the second period was generally the most important of the three in influencing ear development and total dry matter. The lowest water requirement was found where an optimum supply was maintained during the first period with a minimum supply during the last two periods, while the highest was observed where the water supply was kept at the optimum through all three periods.

Farming practice in the sand hills section of Nebraska, J. Cowan (Nebraska Sta. Bul. 156 (1916), pp. 67, figs. 9).—A brief history of the Valentine substation is given, the sand hills section of Nebraska and the farming practices followed are described, and the results of experiments with crops and with crop management are presented.

Alfalfa is reported as the most valuable forage crop for the region, exceeding all clovers, including sweet clover, which was found better adapted to hardpan lands than to the sand hills lands. Alsike with red clover seemed well adapted to the wet valleys of the region. Stands of slender wheat, brome, and western wheat grasses were secured on cultivated ground, but the production of hay was small. Sudan grass gave a yield per acre of 1,667 lbs. of hay on light, sandy soil when sown in rows 21 in. apart, and 1,649 lbs. per acre when sown broadcast.

Among the grain sorghums, the upright-headed dwarf milo maize yielded 11.2 bu. per acre on light soil in 1913, this being the highest yield in three years. Corn under similar conditions yielded 13.6 bu. per acre, the best yielding variety being Minnesota No. 13. Yields per acre of 11.8 bu. of winter rye, 11.5 bu. of emmer, and 11.3 bu. of winter wheat, are recorded.

The leading variety of potatoes was Irish Cobbler. The best depth of planting in light, sandy soil was from 4 to 5 in., the best spacing of rows 42 in., and the best spacing of plants in the row 24 in. Potatoes from seed grown under mulch yielded 13 bu. per acre more than those from seed produced in the ordinary way. On light, sandy soil under a mulch of 6 in. of hay, the yield was increased 50 per cent as compared with ordinary methods of culture.

The data pertaining to horticulture and forestry are noted on pages 835 to 842 of this issue.

The work of the San Antonio experiment farm in 1915, S. H. HASTINGS (U. S. Dept. Agr., Bur. Plant Indus., Work San Antonio Expt. Farm, 1915, pp. 17, figs. 2).—A report is given of work continued along the same general lines followed in preceding years (E. S. R., 33, p. 830). The seasonal conditions are noted, the meteorological observations made at the station from 1907 to 1915, inclusive, are summarized in tables, and experiments relating to rotation and tillage, the culture of corn, cotton, field peas, and flax, and the pasturing of oats are described.

Results from the rotation and tillage work secured thus far indicated that the time of plowing has been of more consequence than the effect of the preceding crop, and that plowing should be done early, at least before January of the year in which the crop is to be planted. Cotton and corn generally gave inferior results when following a crop of sorghum.

A comparison of methods of soil preparation conducted in this connection showed that disking may often take the place of plowing and that fall disking may be preferable to spring plowing. In 1915 cotton on disked corn ground yielded at the rate of 696 lbs. of seed cotton per acre, while cotton on spring-plowed corn ground yielded at the rate of 464 lbs. The average yield of seed cotton per acre in a rotation where cotton was grown on disked corn land from 1910 to 1915, inclusive, is reported as 661 lbs. as compared with 592 lbs. in a rotation in which cotton was grown on spring-plowed corn land and 629 lbs. in the rotation where cotton was planted on corn land plowed in August of the preceding year. In 1915 subsoiling apparently decreased slightly the yields of all crops, and for the period from 1910 to 1915, inclusive, the average yields from all crops were also slightly less on land subsoiled than on land not so treated. The use of manure gave more beneficial results on land used continuously for the same crops than where crops were grown in rotation, and it had a more favorable effect on the yields of cotton than on those of other crops, but in none of the tests was the increased yield sufficient to justify the expense of the treatment.

Field peas planted in the fall of 1914 made a good growth during the winter and produced a heavy crop for turning under in the spring. The quantity of green material produced on the average of five plats was estimated at 10.6 tons per acre. On one plat the peas yielded at the rate of 2,888 lbs. of field-cured hay per acre. In these experiments cotton yields have been less from the plat where rye was used as a green manure than in similar rotations where no green manuring was practiced.

Growing a crop in alternate years with clean fallow between crops was not found profitable in the production of corn, cotton, or oats for grain. The method resulted in lowering the yields of both corn and cotton as compared with the yields of these crops grown continuously on comparable plats.

In studying the effect of rotation and tillage on root rot in cotton, it was found that the disease is less serious in cotton grown in rotation with other crops such as corn or oats than when grown continuously on the same land. On a plat cropped continuously to cotton for seven years 25.7 per cent of the plants died from root rot by the time the first picking was made in 1915, and at the time of the second picking about six weeks later 49.7 per cent of the total number of plants had died. The damage from root rot on this plat has increased each year since 1912 when only about 1 per cent of the plants succumbed. On plats where cotton was grown on fall-plowed land in rotations, including corn, sorghum, or oats, there was little or no root rot. Other results secured indicated that the application of barnyard manure has a tendency to check the spread of the disease. It was further observed that subsoiling appeared to have a tendency to reduce the injury in cotton grown on spring-plowed land, but it is not believed that this effect of subsoiling would offset the cost of the work.

In a variety test with corn the highest yield was made by Laguna, followed by Brazos and Old Glory, both Laguna crosses. In a test of planting corn in rows at different distances and of interplanting with cowpeas it was found that where no cowpeas were planted between the rows the yield of corn rose generally as the distance between the rows increased, the highest yield being obtained where the rows were 7 ft. apart and with 4,078 plants per acre, and the lowest where the rows were 4 ft. apart and with 4,480 plants per acre. When the cowpeas were planted after the corn had a good start the growing of a row of cowpeas between the rows of corn did not lower the yield of corn.

Cotton grown in rows 3, 4, 5, 6, and 7 ft. apart with the plants about 6 in. apart in the row gave an average yield of seed cotton about 50 per cent greater in the 7-foot rows than in the 3-foot rows.

Experiments conducted with varieties of field peas indicated the Golden Vine to be above the average in yielding capacity. Kaiser, Gray Winter, Wisconsin Blue, Andes, and Blue Imperial made an excellent growth and appeared to be well adapted to the conditions.

Results obtained with flax in 1915 indicated that for conditions similar to those at San Antonio northern-grown flax varieties, if sown in the winter, may prove as promising as the imported winter types. C. I. No. 13, the only northern strain grown in nursery rows, appeared most promising early in May. Smyrna flax, C. I. No. 30, grown on a field plat yielded at the rate of 11.9 bu. per acre.

The results of an experiment on using oats for pasture indicated that pasturing as late as March 10 had a detrimental effect upon the yield of both grain and hay. A plat pastured from February 7 to February 20 gave the highest yield of grain but a slightly lower yield of hay than plats which were not pastured.

Farm crops work, A. C. Hartenbower (Guam Sta. Rpt. 1915, pp. 16-21, pls. 2).—A general description is given of work with cotton and forage crops. The requirements of a successful variety of corn for Guam conditions are discussed, and the results of trials with types and varieties of cotton and with grasses and other forage crops are reported.

The highest yield of seed cotton, 1,641 lbs. per acre, was secured from Egyptian Yuma. The Egyptian type, as indicated by station results, appears superior to Sea Island under the prevailing soil and climatic conditions. Observations on late planting and on rateoning of cotton are noted.

Among the grasses tested Para grass gave the best results. Under exceptionally dry conditions it grew about 3 ft. high, although cut about every five weeks from the latter part of April to the end of June. Feterita and Kafir corn were planted November 12, 1914, and January 8, 1915. In the first test feterita was ready for harvesting February 4, 1915, and Kafir corn about 8 days later, while in the second test feterita reached maturity March 23, 1915, and Kafir corn March 28. The first crop of feterita thus required 84 days to mature and the second, which produced considerably less forage, only 74. Soil tests with Paspalum dilatatum indicated that on the better soils this grass will support from two to three times as many cattle as the native grasses. On the poorer soils it was found that heavy pasturing destroys the stand. The cost of planting Paspalum, including plowing and otherwise preparing the soil and hauling and setting the roots, was determined to be about \$16 per acre.

[Breeding work with velvet beans and corn], J. Belling (Florida Sta. Rpt. 1915, pp. CVII-CXXXI, figs. 3).—The plant breeding work pursued during the year was confined largely to inheritance and selection studies with velvet bean hybrids, including the fourth and fifth generations. Special attention was given to the inheritance of mottling of the seed coat and the breeding of selected lines to bring about constancy in this character. The behavior of the character in the different generations of the various crosses is discussed at some length. The different hybrids studied were: Florida × Yokohama, Florida × Chinese, Florida × Lyon, and Lyon × Florida.

It was found that the hybridized seeds on the parent Florida or Lyon plants were indistinguishable in appearance from selfed seeds on the same plant, and the author therefore regards seed mottling as a somatic character of the plant which bears the seeds. The Florida-Lyon crosses showed remarkable variation in dominance in the first generation and some of the second generation plants, but this variation seemed to occur solely with mottling. In the third generation of the Lyon-Florida cross the mottled plants were often

bicolor and more or less inherited the parental amount of pigment, which is considered as proving that there are three genetic differences in this cross concerned with pigment in the seed coat.

Data secured in studying the inheritance of the length of pod in the Florida-Yokohama cross are also reported.

In breeding corn, crosses were made between the best West Indian variety and the best varieties of north Florida, Georgia, and Alabama. Selection was made for pure white, flinty, deep, and fairly large grains, long, compact, and drooping ears, with about twelve straight rows and tightly fitting husks, narrow cob, and two good ears on the stalk. In the fourth generation of a cross between Mosby and Cuban a plant was found meeting all the requirements, but in the fifth generation in 1915 some undesirable qualities appeared which are to be eliminated by further selection.

A cross between Cuban field corn and Black Mexican sweet corn was selected for white, well-wrinkled, translucent grains, ears with about twelve rows, and good growth in hot weather. A type of sweet corn was developed which seems to grow better in central Florida when planted late than either Black Mexican, Stowell Evergreen, or Country Gentleman.

A cross between Mosby field corn and Black Mexican sweet corn was made for the purpose of developing a sweet corn having white, well-wrinkled, translucent, and large grains, and six-rowed, long ears. The selected second-generation stalk was six-rowed, as were all subsequent ears.

Commercial varieties of alfalfa, R. A. OAKLEY and H. L. WESTOVER (U. S. Dept. Agr., Farmers' Bul. 757 (1916), pp. 24, figs. 7).—This describes the commercial varieties of alfalfa as divided into five groups, the common, Turkestan, variegated, nonhardy, and yellow-flowered groups. The history, cultural status, characters, adaptation, and value of each group and the principal varieties and strains it includes are noted. Varieties and strains recommended for various sections of the United States are enumerated, and directions for purchasing seed are given. Seed production and possibilities in breeding are briefly discussed.

Transplanting alfalfa, N. E. Hansen (South Dakota Sta. Bul. 167 (1916), pp. 424-445, figs. 9).—This bulletin discusses in a general and popular way the transplanting of alfalfa by means of transplanting machines and by hand, gives directions for digging, storing, and shipping plants for transplanting, and enumerates the reasons why the practice is desirable.

Report on corn and cotton varieties at the Georgia Experiment Station for 1915, C. K. McClelland (Georgia Sta. Circ. 74 (1916), pp. 8).—The usual variety trials with corn and cotton for the year 1915 are described, and the results of the different varieties are listed.

The 16 varieties of corn under test ranged in yield from 24.3 bu. to 33.7 bu. per acre, produced by Virginia Ensilage and Steinheimer Marlboro, respectively. The strains of Marlboro corn again demonstrated the superiority of the variety. The earlier maturing varieties such as Virginia Ensilage, Mexican June, and Hickory King appeared at the foot of the list.

The yields of 45 short-staple and 5 long-staple varieties of cotton are reported. Cleveland Big Boll ranked first in yield of seed cotton per acre, but considerable variation in the different strains of seed of this variety was observed.

[Cane.—Fertilizer and composition studies], J. M. Scott (Florida Sta. Rpt. 1915, pp. XXIV-XXXI).—A fertilizer experiment with Japanese cane, previously described (E. S. R., 34, p. 831), is reported and the results of six crops grown since 1909 are given in tables. The data presented confirm earlier conclusions and recommendations. A second fertilizer experiment with Japanese cane begun in 1914 is briefly described and the first year's results are tabulated.

Analyses reported of maiden cane (Panicum hemitimomum) at different stages of maturity show that during the early stages of growth this grass is rich in feeding value.

Studies on oat breeding.—IV, Pure line varieties, F. M. Surface and J. Zinn (Maine Sta. Bul. 250 (1916), pp. 95-148, pls. 2, figs. 5).—This bulletin defines and illustrates the meaning of a pure line, discusses the general methods used in the pure-line breeding of cereals, and describes work in oat breeding begun in 1910 with 460 individual oat plants representing 18 different commercial varieties. A method used for correcting the yield of individual plats for differences in soil fertility is also briefly outlined. Similar work has been previously noted (E. S. R., 32, p. 38; 35, p. 33).

By means of selection the number of pure lines in 1915 had been reduced to 12, representing only 3 of the original commercial varieties, Banner, Irish Victor, and Imported Scotch. The results for three years, given in tables, show that these pure lines averaged in yield 80.8 bu. per acre against 75.2 bu. for 11 commercial varieties, only 4 of which gave a better yield than the poorest of the pure lines. In all cases the average yield of the pure lines selected from a given variety exceeded the yield of the parent variety. As the pure lines closely resemble their respective parent varieties in morphological characters, such as type of head, character of grain, and other features, the changes in the physiological characters which result in higher yield are regarded as not necessarily associated with morphological characters in the plant or grain.

Of the 12 pure lines, Maine 340, an Irish Victor selection with an especially stiff straw, a high weight per bushel and per 1,000 kernels, and a relatively low hull percentage, is regarded as the best for conditions of the experiment, although standing second in average yield. Maine 355, a Banner selection, ranked second in value and gave the best average yield of any of the lines, but it has a slight tendency to lodge on heavy soil. Maine 247, 286, and 357 appeared slightly inferior to the rest in yielding capacity. It is stated that each of the 12 pure lines is well adapted to conditions in the southern and central part of Maine, and that, being bred from single plants, they tend to ripen much more evenly and are more uniform in all their characters than most commercial varieties.

Irish potato spraying, H. P. STUCKEY and B. B. HIGGINS (Georgia Sta. Bul. 123 (1916), pp. 115-124, figs. 4).—Spraying tests carried on in 1915 and 1916 are described and the results, including the cost of spraying each season, are reported.

While the outcome of the two years' tests is not regarded as warranting very definite conclusions, it is considered as indicating that early blight may be very destructive and that during such seasons spraying with Bordeaux mixture as well as arsenate of lead may be practiced successfully. Two applications of mixed Bordeaux and arsenate of lead were found sufficient for controlling both early blight and potato beetles on early-maturing varieties, and it is recommended that the first application be made when the plants are about 6 to 8 in. high and the second about three weeks later.

Lime-sulphur versus Bordeaux mixture as a spray for potatoes, IV, M. T. MUNN (New York State Sta. Bul. 421 (1916), pp. 311-317, pl. 1; abs. (1916), pp. 2).—This bulletin describes experiments conducted in 1915 in continuation of work pursued the four preceding years and previously noted (E. S. R., 33, p. 40).

The results are reported as agreeing essentially with those previously obtained, showing that lime-sulphur is harmful rather than beneficial to potatoes. Bordeaux mixture prevented tipburn to a considerable extent, made the foliage

darker green, prolonged the growing period, increased the yield, and materially checked the ravages of late blight caused by the fungus *Phytophthora infestans*, while lime-sulphur aggravated tipburn, dwarfed the plants, shortened the growing period, reduced the yield, and proved valueless as a preventive of the disease. The average results for the five years show an increase of 68.8 bu. of marketable tubers per acre ascribed to spraying with Bordeaux mixture as compared with a decrease in yield of 25.8 bu. ascribed to spraying with lime-sulphur solution.

Culture of rye in the eastern half of the United States, C. E. LEIGHTY (U. S. Dept. Agr., Farmers' Bul. 756 (1916), pp. 16, figs. 8).—This describes varieties of rye adapted to the cotton belt and the Northern States in the eastern section of the country, and discusses the production of the crop. The following varieties are reported as having given an excess of 30 bu. per acre for the three or four years that they were grown at Arlington Farm, Va.: Giant Winter, Abruzzes, Arlington Winter, Virginia Winter, Mexican, Rimpau, Ivanof, and Henry. In the discussion of the producing of the crop the soils adapted to rye, the place of rye in the rotation, the preparation of the seed bed, the use of fertilizers, preparation of the seed, time, method, and rate of seeding, and the methods of harvesting are noted. The pests affecting the crop and their control are also briefly mentioned.

New sorghum varieties for the central and southern Great Plains, H. N. Vinall and R. W. Edwards (U. S. Dept. Agr. Bul. 383 (1916), pp. 15, figs. 7).—A description is given of Dwarf hegari, Improved feterita, Dwarf feterita, White milo maize, and Schrock Kafir corn, and a comparison is shown in a table of the field records of these sorghums at Chillicothe and Amarillo, Tex., from 1913 to 1915, inclusive, and at Hays, Kans., for the years 1914 and 1915. The three-year period included a wet year, a dry year, and one of average weather conditions. The value of the varieties in different portions of the Great Plains is discussed and general conclusions are drawn.

It is pointed out that Schrock Kafir corn has a long growing season and therefore yields best in the southern portion of the Great Plains. While producing good yields under favorable conditions it does not furnish at the same time a good quality of grain, as its seeds contain an appreciable amount of tannin. Dwarf hegari is recommended for the whole sorghum region in Texas lying south and east of the Panhandle. Dwarf feterita and Improved feterita gave better results than ordinary feterita and are regarded as generally promising a larger grain yield than either Dwarf milo maize or Dwarf Kafir corn on the high plains of northwestern Texas, western Kansas, and eastern Colorado. White milo maize produced very satisfactory yields of grain and while the fodder furnished is rather inferior in quality, it is considered worthy of more extensive planting in northwestern Texas, western Oklahoma, western Kansas, eastern Colorado, and western Nebraska.

A study of Colorado wheat, II, W. P. HEADDEN (Colorado Sta. Bul. 217 (1916), pp. 3-46).—The work here reported, conducted in 1915, is in continuation of investigations carried on in 1913 and described in Bulletin 208 of the station, already noted (E. S. R., 33, p. 637). A study of the composition of the wheat plant and the effects of fertilizers are presented, together with a general statement of the weather conditions for the two seasons. No further study of the bacteriology of the soil reported in the bulletin mentioned was made. A summary of the results, including the data collected in 1913, is given.

The land used for these experiments, as determined in 1913, contained a liberal supply of total potash, 101.6 tons in the upper 2 ft. of soil, with approximately 1 ton available at that time. The quantity of hydrochloric acid-soluble potash indicated over 25 tons available. The citric acid-soluble phosphoric acid was

about 1,400 lbs. and the hydrochloric acid-soluble 9,800 lbs. The total nitrogen found in the same depth of soil was 8,240 lbs. While the nitrogen was not considered remarkably high, it was shown that a very considerable portion of it actually existed in the soil in the form of nitric nitrogen at the time of planting, the upper 2 ft. containing nitric nitrogen equivalent to 211 lbs. of sodium nitrate.

The power of this soil to fix nitrogen was discussed in previous publications (E. S. R., 25, pp. 814, 815). It was found at that time that in 27 days a sample of this soil simply kept in a moderately warm room gained 4.82 mg. of nitrogen for each 100 gm. of soil, or 48 parts per million; this was equivalent to the addition of 192.8 lbs. of nitrogen or of about 1,100 lbs. of sodium nitrate to an acre-foot of soil in one month.

In both seasons the effects of irrigation on the distribution of the nitrates were determined. On April 29, 1913, before irrigation, a soil sample in the upper 4 ft. was found to contain nitric nitrogen equivalent to 1,908 lbs. of sodium nitrate, while another sample taken the same day from the same depth of soil contained the equivalent of 471 lbs., but with a total additional equivalent of 721 lbs. in the seventh, eighth, and ninth foot. On June 27, 13 days after irrigation, the upper 4 ft. of three different sections of soil were found to contain 162, 91, and 156 lbs., respectively, with a maximum of 30 lbs. below 4 ft. in three borings taken to a depth of 12 ft., and a minimum of zero. The season of 1913 had a high rainfall in general, but with long periods without any precipitation, while in 1915 the total rainfall was as large again and well distributed in a succession of light showers throughout the season. Soil samples taken at the end of June, 1915, were found to contain, even in the fourth foot, nitric nitrogen as high as equivalent to 48 lbs. of sodium nitrate, while by August 3, at the beginning of the ripening of the grain, the surface foot contained the equivalent of only about 20 lbs., the minimum found in the fourth foot at this time being zero. Samples taken from fallow ground on August 3, 1915, showed a nitric nitrogen content equivalent to 285.5 lbs. of sodium nitrate, while a sample from cropped land taken to the same depth at the same time gave an equivalent of 46.9 lbs. "The crop, either by preventing the formation of the nitrates or by using them up, had made a difference equal to 238.6 lbs. of sodium nitrate in this depth of soil."

Investigations showing the nitrifying efficiency of this soil have been previously noted (E. S. R., 25, p. 814; 30, p. 818). Three sets of soil samples taken from fallow land to a depth of 19 in. on August 1, 1913, showed a nitric nitrogen content equal to 542.43 lbs. of sodium nitrate per acre. The nitric nitrogen of samples taken the same date from cropped land to a depth of 2 ft. corresponding to 101.2 lbs., and samples taken December 4, 1914, to a depth of 19 in. on the same plat, after harvesting a crop of wheat August 6, irrigating the land August 28, and plowing it November 14, gave an equivalent of 299.35 lbs. It is pointed out that the difference in nitric nitrogen as compared with the fallowed land was equal to 243 lbs. of sodium nitrate in favor of the latter, and that the difference between 299.35 lbs. and 101.2 lbs. of sodium nitrate gives an approximation to the difference in the amount of nitric nitrogen in the upper 2 ft. of soil on August 1 and December 4. Studies along this line more closely followed in 1915 gave similar and equally positive results. The cropped land again contained its minimum amount of nitric nitregen about August 1. Data arranged in tables indicate a rapid fall of the nitric nitrogen in the cropped land from the middle of May to the beginning of August, or during the growing period of the plant.

The total nitrogen was also determined and the data secured are given in tables, without interpretation of the results because of the difficulty of obtaining samples of soil varying by less than the amount of nitrogen concerned in

this study. A study of 150 sq. ft. of soil sampled by taking a core from the center of each square foot to a depth of 12 in. brought out the fact that it was rarely the case that contiguous square feet of soil showed so small a difference in total nitrogen as 0.001 per cent. The actual difference reached 0.0354 per cent, or more than 35 times as much as would have a considerable significance in the development of the crop, if present in the form of nitric nitrogen.

A study of the effect on the composition of the plant of different amounts of water applied to the soil, the composition of two series of samples which received 30.77 in. of water in all, 24 in. irrigation and 6.77 in. rainfall, being compared with the composition of 16 series grown with 18.77 in, of water, 12 in. irrigation and 6.77 in. of rainfall, brought out no differences in the amount of nitrogenous compounds in the plants that could be attributed to the varying amounts of water applied. In 1915, when the crop again received about 19 in. of water, differences in the composition of the plants up to the end of July were considered due to the fact that plants were thoroughly moistened by application of water almost daily as the result of the prevailing weather conditions. Later the abundant development of rust as a result largely of the moisture on the plants began to play a still more important part in this direction. The general effect was to suppress all forms of nitrogen present in the plant as well as the ash constituents throughout its growing period. The size of the plants and the percentage of dry matter were not materially different in the two seasons.

The very different weather conditions prevailing during the two seasons are believed to have demonstrated that the observed effects of the fertilizers applied in 1913 are independent of the weather. It is further stated that while the weather conditions of 1915 made great differences in both the nitrogen compounds and ash constituents of the plants, they did not obscure the effect of the nitrogen applied on the total, or the proteid nitrogen, or the silicon, or the ash constituents in general. The same is regarded true with respect to the effects of phosphorus and potassium. It is stated that the effect of the application of nitrogen was to increase the nitrogen in all parts of the plant, to reduce the percentage of dry matter and the percentage of silicon, to increase the percentage of potassium, calcium, and magnesium, as a rule, to increase also the total ash, and to remain neutral relative to the amount of phosphorus in the plant. The application of nitrogen is reported also as increasing the height of the plant, the length of the head, and the color of the plant, but as not increasing the kernels per spikelet. Phosphorus seemed to be indifferent to or possibly tended to depress the amount of the nitrogen in the different parts of the plant, and the same was true of potassium, except that this element showed a stronger tendency to depress the nitrogen, Both phosphorus and potassium depressed the phosphorus in the plant. These effects upon the composition of the plant were apparently not changed by the weather conditions. The effect of the application of nitrogen in the form of sodium nitrate in the production of flinty and often shrunken kernels was not changed in the wet season of 1915. The weather conditions of 1915 as compared with those of 1913 are further considered as having been without material effect on the occurrence of yellow-berry. The attack of rust seemed to affect materially the course of the chemical changes that took place after the early part of August, 1915, as compared with those taking place during the ripening period of the plant in 1913.

Distinguishing characters of the seeds of Sudan grass and Johnson grass, F. H. HILMAN (U. S. Dept. Agr. Bul. 406 (1916), pp. 5, figs. 5).—This bulletin enumerates and describes the distinguishing characters of seeds of Sudan grass and Johnson grass, and points out the apparent exceptions to these characters.

Second annual report of the state grain laboratory of Montana, A. ATKINSON and B. W. WHITLOCK (Montana Sta. Bul. 108 (1915), pp. 129-148, figs. 7).— The work of the year ended September 30, 1915, included the handling of 2,570 seed samples, of which 2,306 were tested for germination and purity, making 160 laboratory and field tests to determine the percentage of germination of hard seeds of legumes, inspecting 35 fields of flax and one of alfalfa grown from pedigreed seed, conducting milling and baking tests of wheat, and collecting data on the more important weeds of the State. The results of the different tests are tabulated, and the number of seed samples of 12 common crops tested for purity and containing seeds of the 50 most common weeds are listed.

The New Jersey seed law, J. P. Helyar (New Jersey Stas. Circ. 59 (1916), pp. 3-12).—The text of the 1916 act regulating the sale of agricultural seeds in New Jersey is given and requirements are explained.

Weed control, J. P. Helyar (New Jersey Stas. Circ. 60 (1916), pp. 3-12).—A popular article, treating briefly of the weed problem in general and presenting notes on the classification of weeds, methods of control including the control of dodder and of weeds in lawns, and the use of chemical weed destroyers.

### HORTICULTURE.

Fungoid and insect pests of the farm, F. R. Petherbridge (Cambridge, England: University Press, 1916, pp. VII+174, figs. 54).—A practical treatise on farm and garden diseases and pests and their control. The work covers general farm crops as well as fruits and vegetables.

[Fruits, vegetables, and lawns in the sand hills], J. Cowan (Nebraska Sta. Bul. 156 (1916), pp. 60-65).—Suggestions are given relative to varieties and cultural practices based upon work conducted at the Valentine Substation.

Suggestions to growers and shippers of fruits and vegetables as to the best methods of preparation, loading, stowing, stripping, and bracing for safe transportation (Com. Ry. and S. S. Refrig., Amer. Assoc. Refrig. Bul. 3 (1916), pp. 31, figs. 27).—A compilation of information dealing with various phases of the transportation problem as affecting the shipment of fruits and vegetables.

Report on the statistics of vineyards, orchards and gardens, and root crops for the season 1915-16, W. L. Johnston (So. Aust. Statis. Dept. Bul. 3 (1916), pp. 6).—A statistical report on the area and production of vineyards, orchards and gardens, and root crops for the season 1915-16, including comparative data for the previous four years.

Guide and catalogue of the Madagascar Experiment Station at Ivoloina (Guide et Catalogue de la Station de l'Ivoloina. Tananarivo: Govt., 1916, pp. 23, pl. 1).—In addition to general information relative to the station, a descriptive catalogue is given of economic plants grown there.

Asparagus in California, the culture, marketing problems, and history, W. F. Bailey (State Com. Market Cal. Bul. 1 (1916), pp. 23).—A short general account of the fresh asparagus and asparagus canning industries of California, including a discussion of methods employed, cost of production, and marketing statistics.

Studies on the dying out of pepper vines in the Dutch East Indies.—II, Pepper cultivation in Banka, A. A. L. Rutgers (Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Lab. Plantenziekten, No. 19 (1916), pp. 36, pls. 16).—In continuation of a previous paper (E. S. R., 35, p. 349) results are given of a survey of the pepper industry in Banka, including the history and extent of the industry, methods of cultivation, and prevalent diseases and pests of peppers.

A genetic study of plant height in Phaseolus vulgaris, R. A. EMERSON (Nebraska Sta. Research Bul. 7 (1916), pp. 8-73, figs. 16).—In this paper the author analyzes the factors concerned in height of plants in beans and discusses the mode of inheritance of these factors as determined by a study of the progeny of crosses between pole and bush beans of varying heights. The methods employed in breeding, making records, etc., are described in detail and a bibliography of cited literature is given.

The results of the investigations as a whole show that pole and bush beans differ in a single character, habit of growth. Bush beans are determinate and pole beans indeterminate in growth habit. The indeterminate habit of growth is fully dominant to the determinate habit. Following the Mendelian ratio the determinate habit is constant in  $F_0$ , while some indeterminate  $F_2$  plants breed true in  $F_0$  and others segregate again into pole and bush plants. In addition to their indirect relation to habit of growth the two characters, number of internodes and internode length, are in a way distinct from habit of growth. There are distinct types of both bush and pole beans in respect to both number of internodes and internode length. Crosses of bush beans of different internode lengths, as well as crosses of pole beans of different internode lengths, result in an intermediate condition in  $F_1$  and a wider range of variation in  $F_2$  with respect to internode length.

In a short pole bean and tall bush bean cross, tall pole beans are dominant in F₁. Some of the pole bean segregates have fewer and shorter internodes than the pole bean parent and some of the bush bean segregates have more and longer internodes than the bush bean parent. Similar results follow when a tall pole bean is crossed with a short bush bean. The dominance of indeterminate over determinate habit of growth is interpreted just as are other simple Mendelian results, namely, on the basis of a single dominant, genetic factor for the difference between the parents in habit of growth. The intermediate height in F1 and the wide range of variation in F2, from a cross between two bush beans or between two pole beans of different heights, are interpreted in accordance with the multiple-factor hypothesis. Segregation into three plants with indeterminate habit to one of determinate habit, accompanied by an increased range of variation in height of both classes of segregates when a short pole bean is crossed with a tall bush bean or tall pole bean with a short bush bean, is interpreted by a combination of the single-factor and the multiplefactor hypotheses, or by what may be termed a modified multiple-factor hypothesis, the modification consisting merely in the assumption of inequality in dominance and inequality in potency between the factors.

The author believes that this modified multiple-factor hypothesis affords a more simple and direct interpretation of the results in these crosses than does the hypothesis of a single unit-difference between all pole and bush beans, which necessitates the further assumption that the unit-factor is modified commonly, though irregularly, in crosses between pole and bush beans.

The fruit industry in New York State, compiled by E. VAN ALSTYNE (N. Y. Dept. Agr. Bul. 79 (1916), pts. 1, pp. 627-981, pls. 2, flgs. 124; 2, pp. 981-1432, pls. 14, flgs. 189).—This bulletin comprises as a whole a manual of information relative to the fruit industry of New York State. The subject matter has been prepared by various horticultural investigators, both within and without the State, as well as by many practical fruit growers. Part 1 treats of the fruit industry of the State in all its phases, followed by detailed information relative to the commercial production and handling of apples. Part 2 treats, in a manner similar to apples, of pears, peaches, cherries, plums, prunes, quinces, grapes, and small fruits. The bulletin concludes with an article on fruits in the home.

Notes on Argentine fruit culture, C. D. Girola (Bol. Min. Agr. [Buenos Aires], 20 (1916), No. 5-6, pp. 364-371, pls. 6).—This comprises descriptive notes on a number of fruits commonly grown in Argentina.

[Progress report on horticultural investigations] (Missouri Sta. Bul. 141 (1916), pp. 32, 33, 34-36).—This comprises concise statements of progress made along various lines of horticultural work during the year ended June 30, 1915.

In the orchard nutrition studies by J. C. Whitten and C. C. Wiggans no data were secured on peaches, spring frosts having killed the buds. In a part of the work, which was conducted in pots containing south Missouri soil, nitrogen applied as a fertilizer seemed to increase the number of apples on young trees just beginning to bear. At the same time apple blight attacked more severely the trees fertilized with nitrogen. No appreciable results were secured with potash or phosphoric acid, either alone or in combination with nitrogen, the complete mixture being somewhat better than the single elements, except nitrogen.

The results of the cooperative spraying experiments have been previously noted (E. S. R., 33, p. 45).

In the work of breeding peaches for hardy sorts by J. C. Whitten a few of the earlier crosses came into bearing. During the past winter a self-fertilized Lewis tree was able to bring 16 per cent of its buds through a temperature of —12.8°, whereas on all of the leading commercial varieties at least 98 per cent were killed and in most cases 100 per cent.

Observations on the self-fertility and self-sterility of fruits by J. C. Whitten and C. C. Wiggans indicate, as previously noted, that the commercial varieties of apples show a tendency to self-sterility, especially in certain years.

Studies on fruit bud development of fruit trees as influenced by treatments and previous crops by C. C. Wiggans were started in 1913 on the varieties Gano, Rome, and Jonathan, the spurs which set fruit being labeled in July. A record of these spurs taken in 1914 shows that a great majority of the spurs on trees of these varieties are not able to bear fruit two years in succession. The work was extended to additional varieties in 1915. During the winter and early spring of 1915 several freezing point determinations of sap from spurs bearing fruit in 1914 and also from spurs not bearing in 1914 were made. In every case the sap from bearing twigs froze at a lower point than from nonbearing twigs. At the same time the variety and the kind of soil seemed to have considerable influence. The sap studies were continued throughout 1915. Some young Jonathan apple trees were etherized at various times to determine the effect on fruit bud formation, but up to June 30, 1915, etherization had not resulted in any increase in sap concentration.

A test of fall v, spring planting of fruit trees by J. C. Whitten has shown the advantage of fall transplanting over spring transplanting to be more marked in the case of cherries than in any other fruit, although previous results indicating the advantage of fall planting over spring planting for other hardy fruit varieties have been confirmed.

Fruit tree root systems, A. B. BALLANTYNE (*Utah Sta. Bul. 143* (1916), pp. 3-15, figs. 5).—This reports a study of a number of root systems of fruit trees removed from an orchard damaged by seepage conditions in the soil.

An examination of the root systems indicate that fruit trees may ordinarily be expected to send their roots deeply into the ground if the water supply is not too plentiful, especially near the surface, and the ground water level is not too high. The natural depth of fruit tree roots as indicated in this study is probably near the height of the tree. The method and amount of watering will alter the general shape of the root system and make it essentially a deep-

rooted tree or a shallow-rooted one. Properly spreading the roots at planting time may assist in developing a more symmetrical root system. In applying irrigation water the amount of water should be sufficient to keep the surface moist without adding to the supply below.

Recent developments in spraying practices, P. J. Parrott (Mass. Fruit Growers' Assoc. Rpt., 22 (1916), pp. 79-120).—A paper, with a discussion following, in which the author considers the spraying problems confronting the fruit growers of New York State and methods that have been employed by the New York State Experiment Station to meet these problems. The subject matter is discussed under the general headings of the plant lice injurious to apple foliage and fruit, insects that factor in the grading of apples, the insecticidal properties of various sulphids and polysulphids, compatibilities of common insecticides, and the cost of spraying in the upkeep of an apple orchard.

A study of variation in apples during the growing season, W. E. WHITE-HOUSE (Oregon Sta. Bul. 134 (1916), pp. 3-13).—This bulletin gives a summarized account of an investigation conducted to determine whether there are more or less definite periods when apples under Oregon conditions make their main increase in bulk and other periods when their characteristic color markings are developed.

Summing up the detailed data secured by measurements of apples representing four distinct pomological groups, the author finds that apples tend to make a gradual increase in diameter from the commencement of growth with a correspondingly greater increase in volume as the diameter increases, and consequently actually greater increases in volume occur during the latter part of the growing season than in the early stages.

In the case of color development there is a time during the middle of the growing season when color is less developed than in the early stages of growth. A large part of the coloring matter of apples is deposited shortly before picking time. From the viewpoint of securing higher color it is suggested that picking could often be delayed several days to advantage.

In view of the steady gradual increase in size the ideal cultural conditions are those which provide a constant supply of moisture. The author also found that the relative size and the general shape as between individual apples in the early stages of growth is maintained to the picking time. Consequently, in thinning apples undesirable shapes and the smaller fruits should be removed.

The packing of apples in barrels and boxes, W. H. Wolff (N. H. Col. Ext. Bul. 7 (1916), pp. 32, figs. 43).—In addition to a technical account of methods of packing apples in barrels and boxes, the author reviews the legal measures which have been taken in this country to regulate the grading and packing of apples. The text of the United States apple grading law and the Massachusetts apple packing and grading law is appended.

Cranberry improvement, F. P. Schlatter (*Proc. Amer. Cranberry Growers' Assoc.*, 47 (1916), pp. 12-16).—In this paper the author discusses methods of improving the cranberry through plant selection and propagation, seed selection and propagation, and crossbreeding, and outlines investigations to be conducted along this line under the direction of the New Jersey Experiment Stations.

The direct bearers of the National School of Agriculture, Montpellier, G. Verge (Ann. École Nat. Agr. Montpellier, n. ser., 14 (1914), Nos. 1, pp. 25-80; 2, pp. 81-168, flgs. 13).—A summary of observations made during the past fifteen years on direct-producing hybrid grapes growing in the Montpellier experimental vineyard, previously noted from another source (E. S. R., 31, p. 238).

The history of the Viticultural Station of Lausanne, 1886-1916, H. FARS and F. Porchet (La Station Viticole Cantonale Vaudoise de Lausanne des Sa Fondation à Son Transfert à la Confédération Suisse, 1886-1916. Lausanne: Dept. Vaud. Agr., 1916, pp. 107, pls. 2, flgs. 12).—This comprises a retrospective study of the Viticultural Station of Lausanne with reference to its organization, investigations, publications, and participation in the development and protection of the Swiss vineyard industry.

Viticulture in South Africa, A. I. Perold (Internat. Inst. Agr. [Rome], Internat. Rev. Sci. and Pract. Agr., 7 (1916), No. 1, pp. 1-30).—A descriptive account in which the author discusses the history of viticulture in South Africa, the distribution of vineyards, climatic and soil conditions, culture, vine diseases and insect pests, methods of fertilization, utilization of American stocks and self-bearers, grafting and nursery work, effects of grafting on the quantity and the quality of the grapes and wine, varieties, methods of wine making, viticultural products, the labor question, government aid for promoting the industry, and statistics.

Investigation on the nitrogen nutrition of the olive, L. Petri (Atti R. Accad. Econ. Agr. Georg. Firenze, 5. ser., 13 (1916), No. 3, pp. 138-147).—The author finds that the nitrogen content of flowering branches on which the flowers were fertile averaged from 2.119 to 2.37 per cent of the dry weight, whereas in flowering branches in which the ovaries were abortive the nitrogen content was only 0.72 to 0.924 per cent of the dry weight. The investigation also shows that where there is only a limited quantity of nitrates in a soil poor in organic matter, there is a large development of mycorrhiza. Where nitrates occur in abundance the rapid growth of the rootlets furnish an important check to the infection of mycorrhiza.

The investigation as a whole suggests that nitrogen should be applied to olive trees in a readily available form, both on account of its effect in producing fertile fruit buds and in view of its influence in checking mycorrhiza. If nitrogen is furnished in less available forms the rootlets grow less rapidly and permit of the invasion of fungus growth.

Citrus experimental grove, S. E. Collison (Florida Sta. Rpt. 1915, pp. XCIX-CI).—In continuation of previous reports (E. S. R., 33, p. 48), measurements are given showing the average gain in diameter of trees from June, 1909, to June, 1915, growing on various fertilizer plats in the citrus experimental grove. The data are accompanied by notes on the condition and treatment of the grove.

Report of plant physiologist, B. F. FLOYD (Florida Sta. Rpt. 1915, pp. XXXII-XLVIII).—Experiments to determine the influence of certain sources of ammonia and phosphoric acid upon the growth of grapefruit seedlings grown in sand and in field soil were continued (E. S. R., 33, p. 48). The results from the sand culture experiments described in 1914 are compared with those secured in 1913 and the following conclusions are deduced:

Dried blood is superior to the other sources of ammonia used for producing vegetative growth. When used in combination with dried blood, phosphoric acid from different sources varies the amount of growth but little. In combination with ammonia from mineral sources, however, phosphoric acid from different sources causes a large difference in amount of growth. Basic slag gave the best results as a source of phosphoric acid when used in combination with ammonia from mineral sources. The acid combination (sulphate of ammonia—acid phosphate—high grade sulphate of potash), produced the smallest amount of growth of any of the combinations, but the amount of growth from this combination was largely increased when lime was added. The amount of growth

produced by dried blood + acid phosphate + high grade sulphate of potash was not increased by the addition of lime. The addition of lime alone to the soil produced a growth greater than that produced by the above-named acid combination, but not so large as that produced by this combination plus lime.

The results secured in the field soil experiments conducted in 1915 were not parallel with those secured in 1914, practically all the fertilizer plats in 1915 showing a better growth than the check plats, whereas in 1914 the majority of the fertilizer combinations produced less growth than the check plats. This is attributed largely to the fact that the experiments were conducted at different times of the year. The results for the two years are here presented without discussion. The work is to be continued.

A comparison of some citrus conditions in Florida, Cuba, and California, H. S. FAWCETT (Mo. Bul. Com. Hort. Cal., 5 (1916), No. 9, pp. 321-337, figs. 10).—In this article the author briefly discusses some of the differences in horticultural conditions and practices in California, Cuba, and Florida, with special reference to citrus culture.

Citrus trees, T. W. Brown and L. H. Gough (Cairo: Min. Agr. Egypt, 1915, pp. 19, pls. 4).—This paper contains instructions for the cultivation and management of citrus trees, together with notes on insect pests found attacking such trees and methods of control.

Report on the work of the Malang Experiment Station for 1915, T. Wurth (Meded. Proefstat. Malang, No. 12 (1915), pp. 23).—A progress report on investigations dealing largely with rubber and coffee.

Keeping chestnuts over winter (Amer. Nut Jour., 5 (1916), No. 4, pp. 43, 52).—This note describes methods employed by three different nut growers in carrying seed chestnuts through the winter.

Studies in Juglans.—III, (a) Further evidence that the oak-like walnut originates by mutation. (b) A parallel mutation in Juglans hindsii, E. B. Babcock (Univ. Cal. Pubs. Agr. Sci., 2 (1916), No. 3, pp. 71-80, pls. 2).—In this paper the author presents further evidence to show that the oak-like walnut (J. californica quercina) originated as a mutant from J. californica rather than as a hybrid between the walnut and oak (E. S. R., 32, pp. 46, 338). A parallel mutation in J. hindsii is also discussed.

Drug plant culture in 1916, W. W. STOCKBERGER (Jour. Amer. Pharm. Assoc., 5 (1916), No. 10, pp. 1068-1075, figs. 5).—A paper on this subject read before the scientific section of the American Pharmaceutical Association at Atlantic City, in 1916.

Roses for the home, F. L. Mulford (U. S. Dept. Agr., Farmers' Bul. 750 (1916), pp. 36, figs. 27).—A general treatise on rose growing for pleasure and for the beautification of the home grounds. Roses for the lawn, border, arbor, trellis, cutting, and other ornamental purposes are considered with reference to varieties, soil preparation, methods of planting, and training. Consideration is also given to methods of propagation and insect remedies. A section on the fungus diseases of roses, prepared by Flora W. Patterson, is included.

Shade trees, hardy shrubs, roses, perennials, and other ornamental plants recommended for Maine, C. L. WILKINS and S. H. EATON (Bul. [Maine] Dept. Agr., 15 (1916), No. 3, pp. 33, pl. 1, figs. 6).—A descriptive list of ornamental plants which the authors have found through years of experience and observations to be adapted to Maine conditions.

Pruning shade trees, H. F. Major (Missouri Sta. Circ. 81 (1916), pp. 6, figs. 3).—A popular circular discussing reasons for pruning, pruning with reference to tree structure, and varieties of trees adapted for planting on lawn and street.

Book of garden plans, S. F. Hamblin (Garden City, N. Y.: Doubleday, Page & Co., 1916, pp. XII+134, pls. 31, figs. 36).—This work contains twenty blue-print plans with directions and planting lists for each, including photographs illustrating the basic idea. The subjects considered are the farm home of five acres, village home of five acres, planting a small suburban lot, shrub planting for a village home, rose garden, bowlder wall with vines, arbor with vines, small informal garden, poppy bed, naturalistic rock garden, natural rock garden, American wall garden, naturalistic water garden, artificial water garden, woodland garden, wild planting, annual garden, formal garden of Japanese plants, border of fragrant flowers, and special color border. A final chapter gives information on the practical side of gardening, the trees, plants, shrubs, vines, etc., for various conditions, cost estimating, time for planting, and other details.

### FORESTRY.

Farm forestry, J. A. FERGUSON (New York: John Wiley & Sons, Inc., 1916, pp. VIII+241, pls. 62, flgs. 5).—This work, which is based largely on the literature of the subject, deals with the care and management and the utilization of the products of the farm woodlot. It has been prepared primarily for use in agricultural colleges and high schools.

County or community working plans as a basis for woodlot extension work, W. D. Sterrett (Forestry Quart., 14 (1916), No. 3, pp. 467-470).—In this paper the author outlines a plan whereby both Federal and state forest agencies may cooperate with other public agencies in the development of county or community working plans with reference to woodlot and forest problems.

New topographic survey methods, J. H. and F. R. Bonner (Forestry Quart., 14 (1916), No. 3, pp. 433-440, pl. 1, figs. 3).—This paper describes new methods in making topographic surveys as developed largely on the National Forests.

A historical study of forest ecology; its development in the fields of botany and forestry, R. H. BOERKER (Forestry Quart., 14 (1916), No. 3, pp. 380-432).—This comprises the introductory portion of a series of investigations in forest ecology carried on in 1914-15 by the author at the University of Nebraska. The present paper includes a discussion of the historical development of plant ecology and silviculture, a historical summary of these subjects, and a bibliography of related literature.

Notes on a method of studying current growth per cent, B. A. CHANDLER (Forestry Quart., 14 (1916), No. 3, pp. 453-460, figs. 2).—The method here described in detail consists in determining the diameter for the last five and ten years for each diameter breast high class and producing a curve through these points for the next ten-year period.

The intermittent annual growth of woody plants, A. B. Stout (Jour. N. Y. Bot. Gard., 17 (1916), No. 201, pp. 147-152, pl. 1).—A popular discussion of various types of annual growth with special reference to intermittent seasonal growth as observed in our common trees and shrubs.

The botanical and chemical characters of the eucalypts and their correlation.—First report of the committee, H. E. Armstrong et al. (Rpt. Brit. Assoc. Adv. Sci., 1915, pp. 97-116, pls. 2).—This comprises summaries of the following investigations conducted with reference to the botany and chemistry of eucalypts on behalf of the British Association for the Advancement of Science: The Botanical and Chemical Characters of the Eucalypts and Their Correlation, by R. T. Baker and H. G. Smith (pp. 97-106); The Development of the Genus Eucalyptus, by R. H. Cambage (pp. 106-108); The Correlation

Between Specific Characters of the Tasmanian and Australian Eucalypts, by R. T. Baker and H. G. Smith (pp. 108, 109); The Cotyledons and Seedling Leaves of the Eucalypts, by C. Hall (pp. 109–113); and Notes on the Evolution of the Genus Eucalyptus, by E. C. Andrews (pp. 113–115). A summary by the investigating committee as a whole is also included. A bibliography of related literature is appended.

Euphorbia tirucalli, G. Scassellati-Sforzolini (Agr. Colon. [Italy], 10 (1916), Nos. 4, pp. 161–186; 5, pp. 217–234; 6, pp. 284–308, pls. 13, figs. 4).—A monograph on this latex-yielding species with reference to its botany and distribution, products, and economic utilization.

Manurial experiments with Hevea rubber, R. D. Anstead (*Planters' Chron.*, 11 (1916), Nos. 12, pp. 132-135; 13, pp. 144-146).—The results are given of manurial experiments with rubber conducted at the Kerala Estate during the years 1914-15. The results for the two years indicate an increased yield from manure properly applied. It is concluded, however, that the experiment must run for several years to determine whether the increased yield will offset the cost of manuring.

[Tree culture in the sand hills section], J. Cowan (Nebraska Sta. Bul. 156 (1916), pp. 7, 8, 55-60).—Some of the more practical results of tree planting experiments conducted at the Valentine Substation are reported, together with suggestions dealing with planting operations, cultural methods, and varieties.

The experiments with trees, which have been conducted since 1911, show that the best quick-growing trees are Norway poplar, cottonwood, and box elder. Of the slower growing deciduous trees the American elm and honey locust have done best. The Russian olive has given fair satisfaction as a lawn tree. Of the conifers bull pines have given the best results. For tree culture in the sand hills country clean cultivation and the preservation of an earth mulch was found to be more essential than watering.

The forestry situation in Virginia, R. C. Jones (Va. Geol. Com., Off. State Forester, Forestry Leaflet 9 (1916), pp. 8, figs. 7).—A brief statement relative to the forest situation and important forest problems of Virginia.

The aims of the new state forestry department, R. C. Jones (Va. Geol. Com., Off. State Forester, Forestry Leaflet 6 (1916), pp. 3-17).—An outline of the proposed activities of the Virginia state forestry department.

Observations on the woods of the Guindos hacienda, F. ALBERT (Bol. Bosques, Pesca i Caza, 3 (1915), No. 1-4, pp. 320, pl. 1, ftgs. 6).—This work comprises as a whole observations and data covering some seven years on the forest and woodlands on a large hacienda in Chile. The information given includes a description of the various tracts and the species comprising them, a large number of tree measurements, and conclusions relative to the management of these woods.

Contribution to the distribution of the wild-growing ligneous plants of Switzerland.—III, Distribution of woody species in the Canton of Grisons, P. K. Hager (Erhebungen über die Verbreitung der wildwachsenden Holzarten in der Schweiz. III, Verbreitung der wildwachsenden Holzarten im Vorderrheintal (Kanton Graubünden). Bern: Schweiz. Dept. Innern, 1916, pp. 331, pls. 6).—This is the third of a series of studies dealing with the native woody flora of Switzerland, conducted under the direction of the Swiss Inspection of Forests, Hunting, and Fisheries and the Botanical Museum of the Federal Polytechnique School. The present study takes up the ligneous plants of the Canton Grisons.

Part 1 discusses the geography, orography, geology, and climate of the region; part 2 comprises a descriptive catalogue of the woody species; part 3

describes various plant combinations and successions and their aspects; part 4 gives an account of the agricultural conditions in the region; and part 5 reviews the principal results of the investigation with reference to land and plant geography. A number of supplementary charts, together with a bibliography on the subject, is appended.

Report of the division of forestry of the Board of Agriculture and Forestry for the fiscal year ended June 30, 1916, C. S. Judo (Haucai, Forester and Agr., 13 (1916), No. 8, pp. 284-286).—A concise report covering the operations for the fiscal year ended June 30, 1916, principally along the line of forest protection and forest extension. At the close of the year the total amount of forest lands in the Territory in forest reserves amounted to 798,229 acres.

Notes on state forestry in Ireland, H. R. MacMillan (Forestry Quart., 14 (1916), No. 3, pp. 461-466).—A popular descriptive account of the organization and activities pertaining to state forestry in Ireland.

Report on the knowledge of forest conditions on the east coast of Sumatra, P. VAN ZON (Boschbouwk, Tijdschr. Tectona, 9 (1916), Nos. 4, pp. 251-268, pl. 1; 5, pp. 349-374; 6, pp. 429-448, pl. 1).—An account of forest types, forest management, and lumbering activities on the east coast of Sumatra.

Annual progress report on forest administration in the Western, Eastern, and Kumaun Circles of the United Provinces for the forest year 1914-15, P. H. CLUTTERBUCK, H. G. BILLSON, and F. F. R. CHANNER (Ann. Rpt. Forest Admin. West., East., and Kumaun Circles [India], 1914-15, pp. 71+LXVII+7).—
The usual progress report relative to the constitution, management, and administration of the state forests in the Western, Eastern, and Kumaun Circles of the United Provinces, including a financial statement for the forest year 1914-15.

All important data relative to forest areas, forest surveys, working plans, forest protection, miscellaneous work, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

Cost of logging large and small timber, W. W. Ashe (Forestry Quart., 14 (1916), No. 3, pp. 441-452, figs. 4).—In this paper data are given to show for several of the different steps of a sawmill operation the comparative cost of handling trees and logs of different sizes, and also to call attention to the field of utility of the results as a factor to be considered in determining the cost of producing lumber and as a potent argument in certain cases in favor of leaving the small trees to grow to a larger size for future cutting. The results here given are recorded merely as preliminary to intensive studies along this line.

Helps in marketing waste, J. T. Harris (Jour. N. Y. State Forestry Assoc., 3 (1916), No. 1, pp. 12-14, fig. 1).—A popular account of assistance rendered by the Forest Service of the U. S. Department of Agriculture, other forest agencies, and lumber organizations in finding a market for and the utilization of waste material resulting from various wood-using industries.

The preservation of wood, G. DE LA PRAILLE (Rev. Gén. Chim., 19 (1916), Nos. 1-2, pp. 1-16, figs. 11; 3-4, pp. 41-50).—A review of the present knowledge relative to methods of preserving wood from decay as developed in different countries.

The preservative treatment of farm timbers, G. M. Hunt (U. S. Dept. Agr., Farmers' Bul. 744 (1916), pp. 32, figs. 17).—This publication supersedes Farmers' Bulletin 387, previously noted (E. S. R., 22, p. 740), the subject matter having been revised and brought up to date. It discusses the nature of decay, methods of prolonging the life of posts without the use of preservatives and by means of preservatives, and methods of prolonging the life of other forms of farm timbers.

# DISEASES OF PLANTS.

The control of experimental conditions in phytopathological research, A. A. POTTER (*Phytopathology*, 6 (1916), No. 1, pp. 81–88).—The author calls attention to the necessity for the improvement of methods of phytopathological research in order that experiments may be more definitely controlled.

Effect of meteorological conditions on development of plant diseases, II, G. N. DOBOGIN (Mat. Mikol. i Fitopatol. Ross., 1 (1915), No. 4, pp. 3-5, fig. 1).— This is the second report (E. S. R., 34, p. 840) on the meteorological conditions in the region of Petrograd in connection with plant diseases. It covers the spring months of 1915.

Report of the assistant plant pathologist, C. D. SHERBAKOFF (Florida Sta. Rpt. 1915, pp. XCIV-XCVIII).—A brief report is given of investigations begun by the author, the principal ones being in connection with seed bed diseases of celery and tomatoes. While a number of diseases of these truck crops are destructive in parts of Florida, the work has been carried on chiefly with damping off. This, the author thinks, is due to several organisms, among them a Rhizoctonia, a Fusarium, a species of Glæosporium, and Sclerotinia libertiana. Brief notes are given on the prevailing fungus diseases of a number of vegetables. These include lettuce drop, early blight of celery, Phomopsis of eggplants, Cercospora spots of peppers, cucumber rust, and tomato rust.

Notes on parasitic fungi in Wisconsin, I, II, III, J. J. Davis (*Trans. Wis. Acad. Sci., Arts, and Letters, 18 (1915), pt. 1, pp. 78–109, 251–271)*.—The three parts of this contribution are supplemental to a provisional list and give somewhat detailed discussion of a large number of forms. Some of these species are claimed to be new, while others are provisionally so considered. Several species not previously reported for Wisconsin are listed, also additional hosts of these fungi. Alphabetical indexes of hosts are also given.

On fungus parasites of cultivated plants, V. KAZANOVSKÏĬ (Khozūistvo, 1915, p. 696; abs. in Mat. Mikol. i Fitopatol. Ross., 1 (1915), No. 4, p. 124).—It is stated that many Russian varieties of wheat and a minority of introduced ones are attacked by yellow rust.

A survey of plant parasites in 1913 in the Province of Tula, N. P. Trusova (Mat. Mikol. i Fitopatol. Ross., 1 (1915), No. 4, pp. 35-56).—During the wet summer of 1913 in the Province of Tula, Russia, the author observed 152 different diseases on cultivated, and 102 on wild, plants. These include many well-known fungus enemies of field and forage crops and of garden, orchard, and forest plants. Several new species are also described.

New species of mycoflora in the Province of Astrakhan, found in 1914, S. Shembel (Szembel) (Mat. Mikol. i Fitopatol. Ross., 1 (1915), No. 4, pp. 107-112, figs. 10).—The author gives descriptions of four species which are considered as new and named respectively Didymosphæria (Didymclla) alhaginis on Alhagi camelorum, supposedly the winter stage of Septoria alhaginis, previously reported by the author (E. S. R., 34, p. 842); Rhabdospora dodartiæ and Hendersonia dodartiæ on Dodartia orientalis; and Cercospora zygophylli on Zygophyllum fabago.

A Gymnosporangium with repeating spores, J. C. Arthur (Amer. Jour. Bot., 3 (1916), No. 1, pp. 40-45, fig. 1).—Evidence is presented and discussed regarding the supposed identity of Uredo nootkatensis and Æcidium sorbi, the name proposed for the new combination being G. nootkatensis.

The physiological relation of the powdery mildews to their hosts, G. M. Reed (Missouri Sta. Bul. 141 (1916), p. 25).—A brief summary is given of investigations of powdery mildews in relation to their hosts, 22 varieties of wheat having been tested, all but 3 of which gave 100 per cent infection. Two varieties

remained entirely immune, while another gave 75 per cent infection. Most of the varieties tested belonged to the species Triticum durum and T. vulgare.

The oat mildew was tested on 6 species and varieties of Avena, and with one exception (A. barbata), these tests gave 100 per cent infection. Additional tests were made with both the wheat and the oat mildew on varieties studied, with results that confirm previous work (E. S. R., 33, p. 244).

Bacterial blights of barley and certain other cereals, L. R. JONES, A. G. JOHNSON, and C. S. REDDY (Science, n. ser., 44 (1916), No. 1134, pp. 432, 433; abs. in Phytopathology, 6 (1916), No. 1, p. 98).—A brief account is given of a bacterial disease of barley which is characterized by water-soaked lesions with a bacterial exudate on the leaf sheaths and glumes. Laboratory and field studies have been made of the organism, which appears to be a species of Pseudomonas.

Similar diseases have been found and studied on wheat, spelt, and rye, and from each of these hosts the causal organism has been isolated and its pathogenicity fully determined. The organisms from these three sources are believed to be all one species which is quite similar to the barley blight organism.

A detailed account of the study of barley blight, together with a technical description of the organism, is expected to appear soon.

Regarding the changes in the chemical composition of rye resulting from the activity of certain Fusarium forms, A. Pomaskii (Mat. Mikol. i Fitopatol. Ross., 1 (1915), No. 4, pp. 77-106).—Analytical and biological study of the disease of grain known in Russia as "drunk bread" is said to have shown that in the cases under investigation F. roscum and F. subulatum were present. It is thought that other species may be concerned in this trouble.

F. roseum and F. subulatum appear to act similarly on grains, dissolving starch and decomposing albumins. Loss of these substances, and in a less degree of others, totaled in cultures one month old 25.1 per cent. Great changes were also noted in the pentosan, fiber, and fat. There was a decrease of the iodin number and an increase of the acid number. Among the products of the decomposition of the albumins was a toxin, probably a nitrogenous glucosid. Further study is to be made of this toxin and of other products of the action of certain Fusarium forms.

Observations on the pathological morphology of stinking smut of wheat, M. F. Barrus (*Phytopathology*, 6 (1916), No. 1, pp. 21-28, figs. 3).—An opportunity having been presented to watch the development of plants in experimental plats in reference to control of the stinking smut of wheat, caused by *Tilletia fatens*, the author made a careful study of the plants from the time they were in bloom until harvest. The symptoms of the various parts of the host as influenced by the parasite are described at length.

Grain smut investigation and control, G. M. Reed, Emma B. Mundy, and N. M. Gibbs (*Missouri Sta. Bul. 141 (1916*), p. 26).—Continuing previous work (E. S. R., 33, p. 245), experiments were conducted to determine the rate of infection of bunt in wheat, the susceptibility of the various species of oats to loose smut, the relation of early and later planting of oats to the amount of smut, and the effect of temperature, soil conditions, depth of planting, and germination of seed on the amount of smut.

Avena strigosa proved to be the only variety of oats immune in all the experiments, while A. sterilis gave the highest percentage of infection. Most of the species of common oats proved susceptible to the loose smut. Late planting, contrary to the belief among plant pathologists, generally resulted in a higher percentage of infection than early planting.

Fungicidal treatment of seed grains, L. MALPEAUX (Jour. Agr. Prat., n. ser., 29 (1916), No. 5, pp. 98, 99).—Reporting results of tests made in 1914, the author states that copper sulphate solutions of 0.5 per cent or more as used

for steeping seed grain decreased germinability, the effect increasing with both the concentration and the duration of contact. The loss of germinability of oats was not over 6 to 7 per cent, that of wheat reaching higher figures. On the whole, preference is given to the copper sulphate when used in connection with lime to decrease its harmful effect.

A pathological alteration in the leaves of Agave sisalana, G. CATALANO (Bol. R. Giard. Colon. Palermo, 2 (1916), No. 4, pp. 225-230).—A brief description is given of a disorder affecting the leaves of A. sisalana, causing discolorations and excrescences. No parasite was found in connection with the trouble, which is thought to be related to climatic, soil, and other conditions.

Violet root rot of alfalfa in Virginia, F. D. Fromme (Phytopathology, 6 (1916), No. 1, p. 90).—Attention is called to the presence in Virginia of the root rot of alfalfa due to Rhizoctonia crocorum (R. violacea). This disease was first noted in a single field in Virginia (E. S. R., 33, p. 544), but this, together with the present record, is said to extend materially the known distribution of the fungus in the United States, as it had not been definitely reported previously from the Atlantic States.

Note on the white spot of alfalfa, C. H. CBABILL (Phytopathology, 6 (1916), No. 1, pp. 91-93, figs. 2).—The occurrence of white spot disease of alfalfa leaves in Virginia is noted. This disease is characterized by rectangular, whitish-translucent spots on the leaves. Affected plants are usually unthrifty and make a poor growth, and it is considered probable that most of them soon die. Upon examination of the root system of the affected plants the upper surface of the crown was always found in a state of decay, and from the diseased tissue was isolated a species of Fusarium and one of Acrostalagmus.

The fact that the crowns of plants affected with white spot always show injury while those unaffected do not has led to the conclusion that crown injury is responsible for these spots.

Melanose of celery, G. N. Dorogin (Mat. Mikol. i Fitopatol. Ross., 1 (1915), No. 4, pp. 57-76, figs. 9).—The author states that celery in Russia is attacked by Septoria petroselini apii, also by a species claimed not to have been known previously and here described as S. apii graveolentis n. sp. The latter is said to cause even more trouble than the former. Both may be found on the same plant. A critical review is given of the species of this group so far as previously reported.

Remedial measures suggested for both diseases include careful selection of seed, treatment of seed with formalin (1:300 for two hours), rejection of plants showing brown spots on cotyledons or leaves, destruction of all diseased material left after harvesting, and deep fall spading of diseased beds.

Cotton wilt in Georgia, A. C. Lewis (Ga. Bd. Ent. Bul. 40 (1915), pp. 18, pls. 8).—Noting publications previously issued on cotton wilt in Georgia, the author gives some of the results secured in this work to date by the Georgia State Board of Entomology, in cooperation with the Bureau of Plant Industry of the U. S. Department of Agriculture.

The fungus of cotton wilt attacks only cotton and okra, though it has been known to survive a ten-year rotation. The employment of rotation, though evidently advantageous, is rendered less effective by the large number of plants, both cultivated and wild, that are attacked by *Heterodera radicicola*. This disadvantage may now be largely met, it is claimed, by use of the Iron variety of cowpea, which is very resistant to nematodes.

It is stated that among the several more or less resistant strains recently developed in this State, wilt-resistant cotton has been obtained within the last five years that is sufficiently early to be grown with profit under the boll-weevil conditions which are expected soon to extend throughout this region.

A disease of cold frame parsley caused by Sclerotinia libertiana, J. A. Mc-CLINTOCK (Virginia Truck Sta. Bul. 18 (1916), pp. 379-384, figs. 3).—A description is given of a disease of parsley due to S. libertiana, with suggestions for its control. The conditions under which parsley is grown for winter markets in cold frames are said to favor the rapid development and spread of the fungus, the plants being started in the open and covered with cold frames that are difficult of ventilation during the freezing weather.

As a result of the observations reported, ventilation of the frames is deemed beneficial in preventing the spread of the disease. Removing diseased plants and drenching the soil with a 40 per cent solution of formaldehyde and sterilizing the soil with steam are also recommended, the latter method destroying the organisms occupying the soil.

A bacterial stem blight of field and garden peas, W. G. SACKETT (Colorado Sta. Bul. 218 (1916), pp. 3-43, pls. 3, figs. 3).—A description is given of bacterial stem blight of field and garden peas that is said to occur generally throughout the San Luis Valley and northern Colorado and to a limited extent in Nebraska, South Dakota, and Utah. The disease is characterized by the watery, olivebrown color of the stems, and by the yellowish, bruised, and watery looking stipules and leaflets. Where a severe outbreak occurs when the plants are young, the stand may be reduced one-third or more.

This blight is said to be caused by *Pseudomonas pisi* n. sp., a technical description of which is given. The organism enters the tissue through the stomata and through wounds produced by mechanical injury, and is pathogenic to field and garden peas, but not to alfalfa, yellow sweet clover, crimson clover, mammoth clover, cowpeas, and garden beans. In the progress of this investigation, varying resistance to attack was noted, and the author states that planting resistant varieties offers the most satisfactory remedy for this trouble, although later planting than usual may somewhat reduce the amount of injury.

Control of the powdery dry rot of western potatoes caused by Fusarium trichothecioides, O. A. Pratt (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 21, pp. 817-831, pl. 1).—The results of an investigation of the powdery dry rot of potatoes are given, the work having been carried on partly in Idaho. Powdery dry rot, due to F. trichothecioides, is said to be the most important storage rot infecting potatoes in the irrigated West. Under ordinary western field conditions, the fungus does not attack the growing potato plant, and potatoes in storage are only attacked through bruises. Planting infected seed potatoes was found to reduce the stand greatly, although a slight amount of infection in the seed pieces did not cause any serious loss. The causal organism is believed to be well distributed throughout western desert soils. It does not develop below a temperature of 2° C. (35° F.), and in dry, well ventilated storage houses, loss would be very slight at temperatures of from 2 to 4°.

When it is necessary to store potatoes in poorly cooled or improperly ventilated storage houses, the disease may be effectively checked by disinfecting the stock, within 24 hours after digging, with a solution of corrosive sublimate or formaldehyde.

Infection of timothy by Puccinia graminis, E. C. Stakman and F. J. Piemeisel (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 21, pp. 813-816).—
In a communication from the Minnesota Experiment Station, the authors report having found it possible by means of artificial inoculations to infect various strains of timothy with P. graminis avenæ. This host is said to exert an appreciable effect on the morphology of the spores of the fungus, reducing them considerably in size. The rust develops subnormally on timothy and the pustules always remain small. These facts are believed to be suggestive as to

the possible origin of P. phleipratensis, which is considered as being probably a biological species.

Treatment of apple canker diseases, J. C. Whitten (Missouri Sta. Bul. 141 (1916), pp. 33, 34).—A brief account is given of experiments for the control of apple canker disease. The diseased tissue was cut out until a rim of healthy tissue was reached, and the area disinfected or treated with mercuric chlorid, copper sulphate, iron sulphate, and paint.

The mercuric chlorid treatment proved the most efficient. It is claimed that canker can be largely eradicated from resistant varieties if treatment is given before a large area is involved. When once the disease has become deep-seated in susceptible varieties, the treatment will not stop it.

Stippen and spray injury, C. H. CRABILL and H. E. THOMAS (*Phytopathology*, 6 (1916), No. 1, pp. 51-54).—Attention is called to the various agents that have been regarded as causing apple fruit spot, or stippen. Among those mentioned are physiological disturbances, various pathogenic fungi, spray injury, mechanical injury, etc.

As a result of the authors' investigations, it is claimed that stippen, or stippenlike spots, that is, depressed, highly colored areas underlaid by a corky mass of dead, brown cells, may be produced in several ways, as by bruising, insect puncture, injected poisons, insufficient water, or any other agent which may kill a few cells before the apple is full grown. The authors consider that the disease is not caused by spray materials as they are commonly applied.

The Phytophthora rot of apples, H. H. WHETZEL and J. ROSENBAUM (Phytopathology, 6 (1916), No. 1, pp. 89, 90).—The authors report the presence on Oldenburg apples, in July, 1915, of peculiar brown lesions. A Phytophthora was isolated from these, which, on comparison, is believed to be P. cactorum. During October and November the same fungus was again isolated from apples purchased in the market of Ithaca, N. Y. While some investigators in Europe have considered the fungus as quite destructive, the authors do not think that it will occasion much injury in this country.

New or noteworthy facts concerning apple rust, N. J. Giddings and A. Berg (*Phytopathology*, 6 (1916), No. 1, pp. 79, 80).—In continuation of investigations (E. S. R., 35, p. 49), the authors present some of the more important facts brought out in connection with the work on the apple rust fungus (*Gymnosporangium juniperi-virginianw*).

In addition to other statements, the authors claim that a severe infection of the apple rust fungus may cause a premature loss of foliage, a decrease in size of the fruit, and a diminution in the vigor of the tree. As a means of control, the destruction of all cedar trees within a radius of  $\frac{1}{2}$  mile around apple orchards has been recommended, but from the authors' observations it is now claimed that this should be done within a radius of 1 mile.

Some new facts concerning fire blight, F. D. Heald (Better Fruit, 10 (1916), Nos. 11, pp. 21, 22; 12, pp. 23-25; Rpt. Wash. State Hort. Assoc., 12 (1915), pp. 31-35, fig. 1).—In amplification of a statement (E. S. R., 34, p. 647) regarding new phases of attack by Bacillus amylovorus, the cause of blossom, twig, fruit, and body blight of malaceous fruit trees, the author describes fire blight of a characteristic type on developing fruits of apple.

This type differs from that due to invasion of the fruit by way of the pedicel (in which the whole fruit is destroyed) inasmuch as the localized, dark, depressed, and sometimes red-bordered lesions do not always extend their area, even under most favorable circumstances. Culture studies showed that many of the bacteria were dead in these fruit spots. While insect punctures doubtless afford entrance in some cases, in others invasions of stomata or lenticels may

have occurred. The important new fact considered as established is the occurrence of leaf lesions, the evidence so far as obtained apparently favoring the view that the epidermis is penetrated by the bacteria.

A study of the brown rot fungus in northern Vermont, H. E. BARTRAM (Phytopathology, 6 (1916), No. 1, pp. 71-78).—As a result of a study of the common brown rot of stone fruits as found in Vermont, the author claims that the fungus causing the disease is that known in Europe as Sclerotinia cinerea. He arrived at this conclusion not only by measurements of the conidia, absence of disjunctors, and the gray color of the conidial tufts, but more especially by the persistent vitality of the conidia through the winter. The conidia, both those already present as well as those produced from the dormant mycelium in mummied fruits, are said to present a danger of early spring infections that has not been generally recognized.

Gummosis in the fruit of the almond and the peach almond as a process of normal life, M. W. Beijerinck (K. Akad. Wetensch. Amsterdam, Versl. Wisen Natuurk. Afdeel., 23 (1914), pt. 1, pp. 531-542, pls. 2; also in ditto, Proc. Sect. Sci., 17 (1914), pt. 1, pp. 810-821, figs. 3).—Studies previously reported by the author with Rant (E. S. R., 17, p. 1146), and by the latter (E. S. R., 19, p. 449), have been followed up by the author, who states that mechanical wounds in growing tissues of Amygdalaceæ are sometimes healed directly, sometimes after developing gummosis.

The chief tissue which is transformed into gum is the young undifferentiated secondary wood. A network of gum canals forms around the wound as a result of stimulus. The network in the large branches is elliptical in outline, the wound being at the lower focus. If the wound is healed the cambium continues to produce normal secondary wood. Continued stimulus continues gum formation. The stimulus spreads from cells dying slowly after being wounded, poisoned, or parasitized, a cytolytic agent passing therefrom into young wood or procambium which may retain this substance and liquefy. It is considered that gummosis is caused by necrobiosis. Young medullary rays and phloem bundles are converted less readily. In the fleshy part of the fruit the gum arises from the conversion of the phloem, the protophloem remaining unchanged.

It is held that although gummosis in these fruits is a part of the normal development, a wound stimulus is nevertheless active as a normal factor. This arises from the tension in the parenchyma of the fruit wall leading to tearing, necrobiosis, and gum formation in the delicate tissue of the phloem bundles. In one view the almond and the peach almond may be considered as pathological species.

Report of the plant pathologist, H. E. Stevens (Florida Sta. Rpt. 1915, pp. LXXVII-XCIII, figs. 2).—The work here reported covers some investigations of citrus diseases and a pecan disease. The citrus disease investigations have been principally on citrus canker, gummosis, and melanose, the major part of the work having been confined to citrus canker.

In continuation of an investigation of gummosis, inoculation experiments with different organisms have been undertaken, but from six series of these experiments negative results have been obtained. There appears to be some evidence that the disease spreads in the grove under natural conditions. Some experiments for control of gummosis are briefly reported upon, in which the value of Bordeaux paste, lime and sulphur paste, and commercial lime-sulphur solutions were tested, the diseased areas being scraped and covered with the disinfectant, or completely cut out and painted over with it. The results from the treatment, while somewhat favorable, are considered to be only tentative and are to be repeated.

Pruning experiments for control of melanose have been continued, and where the trees were carefully pruned a higher percentage of first-class fruit was obtained.

In connection with the investigations of citrus canker, the author refers to a previous publication (E. S. R., 32, p. 345) in which it is stated that the cause of this trouble is a fungus belonging to the genus Phyllosticta. Subsequent to that publication, inoculation experiments gave negative results, while suspensions of a mixture of this fungus with bacteria isolated from cankered spots produced the disease. This led to the belief that the disease is due to bacteria, and this was soon after shown by Miss Hasse (E. S. R., 33, p. 149). The constant association of the fungus with the canker is not readily explained, but the author believes it may be a secondary agent in the enlargement of the spots. The investigations now in progress include cultural reactions of the organism, *Pseudomonas citri*, its relation to the host plant, and its ultimate effect on the citrus tree.

Brief notes are given on the stem end rot, citrus scab, and withertip of citrus trees.

A study of the pecan disease was begun on account of the serious injury reported from various localities of the State. This disease was previously noted (E. S. R., 23, p. 446) and the name dieback given it on account of the death of the twigs and limbs of the trees attacked. The disease has been studied in the field and the laboratory, and specimens usually show the presence of a number of fungi. One of these has been identified as Botryosphæria berengeriana, which seems to be quite constantly associated with the disease, and inoculation experiments with the fungus have produced characteristic symptoms in most instances. Experiments for the control of this disease are in progress, cutting out diseased parts and applying Bordeaux mixture or lime sulphur solution being tested.

Some bark diseases of citrus trees in Florida, J. G. GROSSENBACHER (*Phytopathology*, 6 (1916), No. 1, pp. 29-50, figs. 9).—A description is given of a number of diseases of citrus trees, together with suggestions for their treatment. Among those described are gummosis, foot rot, crown rot, dieback, withertip, and canker.

The cause of coconut bud rot, J. R. Johnston (Estac. Expt. Agron. Cuba Bol. 27 (1916), pp. 3-101, pls. 15, figs. 6).—In a further report on the coconut bud rot (E. S. R., 26, p. 649; 33, p. 150), associated with the presence of an organism which appears to be practically identical with Bacillus coli, the present apparent range of the disease is said to include many parts of both eastern and western Cuba, western Jamaica with a few cases in the eastern portion, the Cayman Islands, British Honduras, northern and eastern Trinidad, and British Guiana.

Direct inoculation gave positive results both with the organism taken from diseased tissue and with that of animal origin. It is thought that rots of the coconut palm previously ascribed by other writers to other causes may be shown to be due to the same cause as the bud rot.

The various fungicides are ineffectual as remedial agents, but precautionary measures have given good results in most cases.

Fungus diseases of coffee in Porto Rico, G. L. FAWCETT (Porto Rico Sta. Bul. 17 (1916), Spanish ed., pp. 31, pls. 8).—This is a Spanish edition of the bulletin previously issued (E. S. R., 32, p. 645).

A withertip of fir, F. W. Neger (Naturw. Ztschr. Forst u. Landw., 14 (1916), No. 3-4, pp. 121-127, figs. 4).—A withertip of fir is described. It appears to be related to frost injury and to be associated frequently with Nectria cucurbitula and more so with Dermatea eucrita.

Horse-chestnut anthracnose, R. G. Pierce and C. Hartley (*Phytopathology*, 6 (1916), No. 1, p. 93).—The authors report the presence in 1914 of a species of Colletotrichum on the petioles, midribs, and veins of the leaflets of the horse-chestnut. An ascomycete was later isolated from living leaves showing anthracnose, and the authors are led to believe that the ascomycete and the Colletotrichum are identical and should be referred to Glomerella cingulata.

The leaf blotch disease of horse-chestnut, V. B. Stewart (Phytopathology. 6 (1916), No. 1, pp. 5-19, pls. 3, fig. 1).—The author gives a description of the leaf blotch disease of horse-chestnut, discussing its etiology and describing the development of the various stages of the fungus, which is provisionally called Guignardia asculi n. comb. As a result of inoculation experiments, Esculus hippocastanum and E. glabra were readily infected, but E. parviflora was not.

The more economic phases of this leaf spot and its control have been previously noted (E. S. R., 35, p. 154).

Identity of Peridermium montanum with P. acicolum, G. G. Hedgeock (Phytopathology, 6 (1916), No. 1, pp. 64-67).—As a result of inoculation experiments with P. montanum from Pinus contorta, the author was able to produce the Coleosporium stage on Aster conspicuus. This is considered proof that Peridermium montanum is the acial stage of C. solidaginis, from which it follows that P. montanum is identical with P. acicolum. The author considers P. montanum simply a western form of P. acicolum. The fungus is known to occur in five northwestern States and two Provinces of Canada.

Inoculation experiments with Peridermium montanum, J. R. Weir and E. E. Hubert (*Phytopathology*, 6 (1916), No. 1, pp. 68-70).—As a result of field and greenhouse inoculation experiments performed on 3 plants of Aster and 4 of Solidago with eciospores of *P. montanum*, the typical Coleosporium form was obtained. This is said to be the first time that successful inoculations have been reported on species of Solidago.

## ECONOMIC ZOOLOGY-ENTOMOLOGY.

The technique of forest protection against animals, K. Eckstein (Die Technik des Forstschutzes gegen Tiere. Berlin: Paul Parey, 1915, 2. rev. ed., pp. VII+254, figs. 54).—A brief account is first given of the animal enemies of forests and protection from them (pp. 1-18). Following this the work takes up the combating of vertebrate animal pests (pp. 19-80) and of injurious arthropods (pp. 80-243).

The birds of North and Middle America, R. Ridgway (U. S. Nat. Mus. Bul. 50 (1916), pt. 7, pp. XIII+543, pls. 24).—This part of the work previously noted (E. S. R., 30, p. 851) deals with the Cuculidæ, Psittacidæ, and Columbidæ.

The small friends of agriculture, J. W. Da Costa (Os Pequenos Amigos da Agricultura. Sao Paulo: Govt., 1914, pp. 118, figs. 31; rev. in Auk, 32 (1915), No. 4, pp. 518, 519).—This work treats of the small animals, especially birds, that are of economic value in the State of Sao Paulo, Brazil.

The upper limit of temperature compatible with life in the frog, A. T. CAMERON and T. I. BROWNLEE (Proc. and Trans. Roy. Soc. Canada, 3. ser., 9 (1915), Sect. IV, pp. 67-84).—This is in continuation of the investigations relating to the limits of temperature compatible with life in the frog (E. S. R., 34, p. 751).

"The experiments in air lead to the unexpected conclusion that the highest temperature at which Rana pipiens can maintain life indefinitely is about 18° C. (64.4° F.) while a temperature a degree or two higher will prove fatal within a few days. The fatal temperature is to a great extent a function of time, varying from 19 or 20 to 39 or 40° as the time is shortened."

Bibliography of Canadian zoology, 1914, E. M. WALKER (*Proc. and Trans. Roy. Soc. Canada*, 3. ser., 9 (1915), Sect. IV, pp. 307-318).—This annotated list (E. S. R., 34, p. 651) covers the literature exclusive of entomology.

Bibliography of Canadian entomology for the year 1914, C. J. S. BETHUNE (Proc. and Trans. Roy. Soc. Canada, 3. ser., 9 (1915), Sect. IV, pp. 263-278).—This continuation (E. S. R., 33, p. 553) lists 134 articles.

Report of entomologist, J. R. Watson (Florida Sta. Rpt. 1915, pp. XLIX-LXXVI, figs. 7).—A detailed report is first given of studies of the velvet bean caterpillar (Anticarsia gemmatilis), a preliminary account of which has previously been noted (E. S. R., 34, p. 358). Technical descriptions are given of its several stages, including six larval instars.

The moths make their appearance at Gainesville about the middle of August. The larvæ, which become abundant by September 1, feed only on the various species and varieties of the velvet bean (Stizolobium), the kudzu vine, and the horse bean (Canavalia). The eggs, which are placed separately usually on the underside of the leaves or on the tender shoots, hatch in about three days in September. The young caterpillar feeding on the lower surface skeletonizes the leaf by eating all the soft material but leaves the veins intact. After the second instar it consumes the whole leaf except the larger veins and midrib. From three to four weeks are required for the completion of its larval life. The pupa is formed in an earthen cell usually barely beneath the surface of the soil. Ten to eleven days are passed in this stage in September, some 21 days in November, and as high as 47 and 48 days for two individuals that emerged in January.

The species apparently does not winter over even in the central parts of Florida but works northward each summer from south Florida.

Several predacious enemies are mentioned but parasites appear to be of little importance, a single chalcidid having been reared from a hundred pupæ and none from hundreds collected in the field. A disease due to *Botrytis rileyi* nearly exterminated the caterpillars in fields at Gainesville in October, 1914. While the disease appears almost yearly it too often gets started too late to save the velvet beans. The lime-sulphur-lead arsenate spray, previously developed (E. S. R., 33, p. 58), controls the pest when applied in time.

The Florida flower thrips [Euthrips] (Frankliniella tritici projectus) has been studied by the author. Three years' observations and experiments with deciduous fruit trees show that if sufficiently abundant it will cause the deformation or even the destruction of leaves and fruit, the general character of its injury being similar to that of the pear thrips.

On citrus the addition of tobacco extract (2.7 per cent nicotin) to limesulphur being used for citrus scab at the rate of 1 part to 100 of the limesulphur resulted in the destruction of at least 90 per cent of thrips in the blossoms. There appeared to be a considerable increase in the fruit on sprayed over unsprayed trees and the sprayed fruit had a more healthy look.

In further notes on the camphor thrips (Cryptothrips floridensis) it is stated that the species has been received from Ceylon. Anthothrips floridensis is said to have been common during March on the blossoms of some Mexican avocados, most of which they ruined. It attacks the stamens and pistils similar to the flower thrips.

An outbreak of the cottony cushion scale at Key West was controlled by the introduction of the vedalia. Notes are also given on several miscellaneous insects, including the green shield scale (*Pulvinaria psidii*) which severely infested the wild rubber tree (*Ficus* sp.) at Miami in July.

Thirteenth annual report of the state entomologist of Montana, R. A. Cooley (Montana Sta. Bul. 109 (1916), pp. 149-161, fig. 1).—The insect pests of

1915 are briefly discussed and recorded. Some of the more important species, including the army cutworm (*Chorizagrotis auxiliaris*), etc., are next considered more at length.

The amount of damage caused by insects during the year is said to have been the greatest recorded by the state entomologist. Grain pests were especially abundant, the army cutworm alone having destroyed at least 100,000 acres of grain. The spotted fever tick (Dermacentor venustus) appeared in eastern Montana in large numbers and a number of cases of spotted fever were reported from that locality for the first time.

Proceedings of the Entomological Society of Nova Scotia, 1915 (Proc. Ent. Soc. Nova Scotia, 1915, pp. 107, pls. 2, figs. 10).—Among the papers here presented are the following: Some Hemiptera Attacking the Apple, by W. H. Brittain (pp. 7-47); The Brown-Tail Moth in Nova Scotia, by G. E. Sanders (pp. 47-53); The Apple Maggot in Nova Scotia, by C. A. Good (pp. 54-78); Bud Moths in Nova Scotia (pp. 84-87), Fruit Worms or Apple Worms in Nova Scotia (pp. 87-89), The Codling Moth in Nova Scotia (p. 90), The Cankerworm in Nova Scotia (pp. 91, 92), and The Tussock Moth in Nova Scotia (pp. 93, 94), by G. E. Sanders; Parsnip Webworm (Depressaria heracliana), by C. B. Gooderham (pp. 94, 95); Hydræcia micacea as a Garden Pest, by W. H. Brittain (pp. 96, 97); The Oblique Banded Leaf Roller, Archips rosaceana, by A. G. Dustan (pp. 100-102); and A Partial List of the Lepidoptera Observed In and About Truro, Nova Scotia, from July 7 to August 4, 1915, by E. C. Allen (pp. 103-107).

The paper by Brittain on apple insects deals at length with the more important aphidids, etc., attacking the apple, namely, the green apple aphis, the rosy apple aphis (*Aphis sorbi*), the woolly apple aphis (*Eriosoma lanigera*), the rose-leaf hopper (*Empoa rosæ*), the black apple leaf hopper (*Idiocerus fitchi*), including details of life history studies, and a number of other pests.

Important insects which may affect the health of men or animals engaged in military operations (U. S. Dept. Agr., Office Sec. Circ. 61 (1916), pp. 24, figs. 15).—This consists of brief descriptions of the insects which annoy or affect the health of men or animals engaged in military operations, with information regarding their control, particularly as applied to the Southwest.

A classification of our limnephilid caddice flies, N. Banks (Canad. Ent., 48 (1916), No. 4, pp. 117-122).

"White ants" as pests in the United States and methods of preventing their damage, T. E. SNYDER (U. S. Dept. Agr., Farmers' Bul. 759 (1916), pp. 20, flgs. 14).—A popular summary is given of the termites, the nature of their injury, and preventive and remedial measures.

Report on the inoculation of locusts with Coccobacillus acridiorum, J. B. ROBER (Bul. Dept. Agr. Trinidad and Tobago, 14 (1915), No. 6, pp. 197, 198).—Inoculation experiments in Trindad with Venezuelan migratory locusts (Schistocerca paranensis) and the giant Trinidad locust (Tropidacris dux) showed C. acridiorum to be virulent for both species and that its virulence can be increased by passage through a series of locusts.

A new species of Heterothrips from eastern United States, J. D. Hood (Ent. News, 27 (1916), No. 3, pp. 106-108).

The Rutherglen bug (Nysius vinitor), W. W. FROGGATT (Agr. Gaz. N. S. Wales, 27 (1916), No. 4, pp. 270-272, pl. 1).—This hemipteran, after having been comparatively harmless for some years, is said to have been one of the most serious pests during 1915-16. It has been reported, on the coast as well as inland, as damaging fruit, field crops, and even flower gardens.

Some 1915 notes on a few common Jassoidea in the central Mississippi Valley States, E. H. Gibson (Canad. Ent., 48 (1916), No. 5, pp. 177-179).

[Studies of the body louse (Pediculus vestimenti)] (Ztschr. Hyg. u. Infektionskrank., 80 (1915), No. 2, pp. 289-322, pl. 1, figs. 3).—Two papers (1) A Contribution to the Knowledge of the Biology of the Body Louse and Its Control (pp. 289-298) and (2) The Combat of the Body Louse (pp. 299-322) are presented by E. Widman and B. Heymann, respectively.

Control of the velvet bean caterpillar, J. R. Watson (*Florida Sta. Bul. 130* (1916), pp. 49-58, figs. 9).—The data here presented are substantially noted from another source on page 852.

It is recommended that when early varieties of velvet beans, such as the Chinese, can be grown a strip around the edges of the field be sown with the Florida variety as a trap crop. This crop should be sprayed or dusted with lead arsenate every two weeks during the caterpillar season, and when it is necessary the main crop should be similarly treated.

Life history studies of Cirphis unipuncta, the true army worm, J. J. Davis and A. F. Satterhwait (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 21, pp. 799-812, pl. 1, figs. 2).—A report of studies of the biology of this commonly injurious and well-known pest conducted at La Fayette, Ind.

Moths of this species, which were first observed on the night of May 13 feeding on the honeydew from insects on white oak, are thought to have been the adults of hibernating larve. Observations indicate that at La Fayette three complete generations may occur annually and that in some seasons a partial fourth generation may occur. Technical descriptions are given of its immature stages, including six larval instars. The period passed in the last larval instar was approximately two and one-half times as long as any of the previous instars and the amount of foliage eaten was nearly seven times as much as in the fifth and more than 80 per cent of all the foliage eaten during the entire larval period. It is estimated that with 8,890 corn plants to an acre it would require 21,473 worms to destroy an acre of corn 2 ft. high, or the progeny of but some 40 females.

For 100 individuals recorded the egg stage approximated 6 days, the larval 26, and the pupal stage 21 days. In one instance a larva was observed to molt six times. The largest number of eggs laid by a single female was 254, though examinations showed that the bodies of some females contained more than 800.

Observations on the life history of the army cutworm, Chorizagrotis auxiliaris, R. A. Cooley (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 23, pp. 871-881).

At the Montana Experiment Station oviposition was observed from September 30 to October 12, but may have commenced some weeks prior to that time. The eggs, which were deposited upon the bare soil, hatched in about nine days indoors but hatching may be delayed by lack of sufficient moisture. The larvæ feed for a variable period in the fall and the winter is passed in a partly grown stage. In the spring they feed until about the first week in April, then enter the ground to pupate. The adults emerge from the latter part of June to the middle of July and live over until fall, the ova developing from food obtained as adults. Thus in Montana the species is single-brooded.

The life history of Gelechia gossypiella from the time of the cotton harvest to the time of cotton sowing, L. Gough (Min. Agr. Egypt, Tech. and Sci. Serv. Bul. 4 (1916), pp. 16).—An account of the pink boll worm based upon studies in Egypt. See also previous notes (E. S. R., 30, p. 755; 32, pp. 152, 449; 33, p. 655).

The nature of the damage done by the pink boll worm (Gelechia gossypiella), L. Gough (Min. Agr. Egypt, Tech. and Sci. Serv. Bul. 2 (1916), pp. 6).—This paper relates to the damage caused by the pest above noted.

Aphidoletes meridionalis, an important dipterous enemy of aphids, J. J. DAVIS (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 23, pp. 883-888, pl. 1, figs. 4).—This cecidomyiid, first described in 1908, has been found to be of economic importance in at least six Central States through its feeding in the larval stage upon almost any species of aphid available.

The eggs are deposited on foliage among a colony of aphids in clusters of from 1 to 12, or may be deposited upon the dorsum of the aphid itself. Records kept of two females show 116 and 125 eggs to have been deposited. Upon hatching out the larva attacks the nearest aphid. After sucking the body fluids and killing one, it continues to move on to another until full grown. After from 7 to 11 days, which are required for the development of the larva, a loose cocoon is spun, shortly followed by pupation, usually at or near the surface of the ground. The length of the pupal stages varies from 6 to 9 days. Oviposition, which apparently only occurs at night, was observed to continue for a period of 10 days, the length of life of the adult under the same conditions being 14 days. The total length of its life cycle was observed to vary from 15 to 29 days. Hibernation takes place in the larval stage and possibly also as pupæ within the cocoons.

Mosquito control in Panama.—The eradication of malaria and yellow fever in Cuba and Panama, J. A. Le Prince and A. J. Orenstein (New York and London: G. P. Putnam's Sons, 1916, pp. XVII+335, pls. 58, figs. 20).—This work, by the chief sanitary inspector of the Isthmian Canal Commission and his assistant, presents a detailed account of the manner in which mosquitoes have been held in check in the Canal Zone. The work is prefaced by a brief introduction by L. O. Howard of the U. S. Department of Agriculture. The first of the two parts deals with the antimalaria campaign (p. 3-228) and the second part with the yellow fever campaign (pp. 229-324). The work includes maps of the Isthmus, showing the completed canal; of Gatun, showing the Anopheles propagation area and houses where stained specimens were recaptured; and of Havana, showing the yellow fever district. A complete index to the subject matter is included.

New species of Asilidæ from southern California, F. R. Cole (Psyche, 23 (1916), No. 3, pp. 63-69, pls. 3).

The cabbage maggot, its biology and control, W. J. SCHOENE (New York State Sta. Bul. 419 (1916), pp. 99-160, pls. 8, figs. 3).—This bulletin is based upon observations commenced in 1906 and extending over the eight following seasons. Data relating to its injury and control work with cabbage seedlings grown under cheesecloth and with truck crops have been previously noted (E. S. R., 25, p. 38; 31, p. 352).

This pest appears to be limited to the North, serious injury having rarely been reported south of latitude 45° in this country and latitude 40° in Europe. The winter is passed in the pupal stage, the adults commencing to appear about the time the Windsor cherry blossoms, and continuing to emerge over a period of four or five weeks. Those that appear first are largely from the fall brood of larvæ, but a few originate from the first and second broods of larvæ of the previous summer. When conditions are favorable there are at least three broods and perhaps a partial fourth brood. The eggs, which are deposited on or near succulent cruciferous plants, hatch in from three to five days. The larva, feeding upon the root, matures in from 18 to 20 days and then enters the soil to pupate. The pupal stage may last from 12 to 18 days or be prolonged for an indefinite period of several months, depending upon moisture and temperature conditions, so that it may be one, two, or three brooded. It is thought that oviposition commences within three to five days after the adults emerge. It is

pointed out that the activities of this insect during the autumn when feeding upon turnips and sprouted cabbage have been largely overlooked. The author's studies show that the presence both in the spring and fall of large acreages of succulent cruciferous roots is a condition necessary for the cabbage maggot to occur in great numbers.

The principal enemies are staphylinids of the genus Aleochara, the cynipid parasite *Pseudoeucoila gillettei*, and a mite of the genus Trombidium.

Control measures include screening for the protection of seed beds, tar-paper disks for the protection of early cabbage, the removal of all crop remnants when the cruciferous crops are harvested, and the destruction of cruciferous weeds.

The cabbage maggot and its work, F. H. Hall (New York State Sta. Bul. 419, popular ed. (1916), pp. 3-8, pls. 2).—A popular edition of the above.

Studies in flies.—II, Contributions to the study of specific differences in the genus Musca, P. R. Awati (Indian Jour. Med. Research, 3 (1916), No. 3, pp. 510-529, pls. 19, figs. 6).—In this second paper (E. S. R., 35, p. 660), the author presents a comparative study of the genitalia in different forms of calyptrate flies and his conclusions relative to the homologies of the parts in this group.

The life history of Bdellolarynx sanguinolentus, J. L. MITTER (*Indian Jour. Med. Research*, 3 (1916), No. 3, pp. 538-540).—The breeding habits of this fly, here reported, resemble in general those of *Hæmatobia sanguisugens* previously noted (E. S. R., 35 p. 760).

Destruction of the tobacco beetle (Lasioderma serricorne), D. B. MACKIE (*Trop. Agr.* [*Ceylon*], 46 (1916), No. 3, pp. 170, 171).—This briefly reports tests and calls attention to the advantages of the vacuum method of fumigation.

New species of the family Ipidæ, J. M. SWAINE (Canad. Ent., 47 (1915), No. 11, pp. 355-369, pls. 2; 48 (1916), No. 6, pp. 181-192, pl. 1).—The host plants recorded of several of the forms here described as new are as follows: Ips perroti from Pinus resinosa on Perrot Island, Quebec; Dryocætes pseudotsugæ from Douglas fir at Stanley Park, Vancouver; Phlæosinus pini from Pinus divaricata in the Riding Mountains, Manitoba; P. hoppingi from cedar limbs in California; P. vandykei from cedar limbs at Huckleberry Meadow, Cal.; Hylastes ruber from bark of dying Douglas fir in British Columbia; Pityokteines elegans from Pinus monticola in Oregon and California; Orthotomicus lasiocarpi from Abies lasiocarpa and Larix americana in British Columbia and Alberta, respectively; O. ornatus from Arizona and Oregon and from Pinus ponderosa and P. jeffreyi in California; I. chagnoni from Picea canadensis and Pinus strobus from Ontario and Quebec Provinces; and I. vancouveri from P. monticola on Vancouver Island and in British Columbia.

Apicultural notes, P. Nelson (Guam Sta. Rpt. 1915, pp. 41-43).—The year under report is said to have been a very satisfactory one for the beekeeper. A record of production by nineteen colonies located at Yigo showed that 1,680 lbs. of surplus honey were extracted from January to May, or an average 88 lbs. per colony. A colony placed at Santa Rosa in December by dividing increased to four fairly strong colonies by May and produced 224 lbs. of surplus honey, averaging 56 lbs. of honey in addition to the increase of three colonies. The single colony of honeybees introduced from Hawaii in 1907 has thrived so well that there are now thousands of colonies of wild bees in hollow trees throughout the forests, the progeny of this single queen.

A method of removing honey and bees from hollow trees without cutting the tree, which has been practiced by the author with much success, is described. During the previous year he removed nine colonies from trees within a radius of half a mile by this method, one of which produced over 250 lbs. of honey.

Thersilochus conotracheli, a parasite of the plum curculio, R. A. Cushman (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 22, pp. 847-856, pl. 1, flgs. 9).—Observations made at North East, Pa., of the biology of this ichneumonid parasite are reported, together with descriptions of its immature stages. The species was first described in 1871 from New Jersey and is known to occur also in Connecticut, New York, Pennsylvania, Illinois, Missouri, Kansas, and Michigan. During the seasons of 1914 and 1915 it was by far the most abundant and effective parasite of the plum curculio at North East.

It is only know to attack this one host and is single-brooded. The adult reaches maturity as early as August 24 in New York State, but does not leave the cocoon until the following spring, from late May to the middle of June. The female parasite deposits a single egg within the young curculio through the curculio oviposition scar. The maximum period of incubation is thought to be six days. The larva passes most of its life as an internal feeder, but when nearly full-grown leaves the host and becomes temporarily an external feeder. In this stage it passes four molts, the first taking place, as a rule, after the host has constructed its pupal cell, and the other three follow within a period of ten days. Pupation occurs in about four or five days after the construction of the cocoon.

The parasite apparently does not commence to oviposit until some time after the curculio has begun its attack on the fruit, thus does not control the early curculio larvæ. In 1915 its emergence at North East was retarded by the cold, wet season, so that only the latest of the larvæ were attacked, practically all of which were parasitized.

A new genus of Elophidæ from the United States, A. A. GIRAULT (Ent. News, 27 (1916), No. 4, pp. 152-154).

A new genus of pteromalid chalcidoid Hymenoptera from North America, A. A. Girault (Canad. Ent., 48 (1916), No. 7, pp. 246-248).

Revision of the parasitic hymenopterus insects of the genus Aphycus, with notice of some related genera, P. H. Timberlake (Proc. U. S. Nat. Mus., 50 (1916), pp. 561-640, pls. 6).—Forty-three species of Aphycus are recognized, of which 14 are described as new, namely, Aphycus maculipennis reared from Lecanium corylifex at Lawrence, Mass.; A. albicornis reared from Pulvinaria sp., at Ikeda, near Kobi, Japan; A. schwarzi collected in the Santa Rita Mountains, Arizona; A. rileyi reared from Lecanium sp. on Japanese persimmon at Millheim, Tex., from an unknown host on sumach at St. Louis, Mo., from L. corni at Ithaca, N. Y., and at Guelph, Ontario, and also collected at Lansing, Mich., and South Kirtland, Ohio; A. subfasciatus reared from L. cerasifex on elm at Columbus, Kans.; A. similis reared from a lecanium on Japanese persimmon at Millheim, Tex.; A. physokermis reared from Physokermes insignicola at Santa Maria, Cal.; A. melanostomatus reared from a lecanium on linden and oak in Denmark and from L. fuscum in England; A. kingi reared from Pulvinaria sp., Lawrence, Mass.; A. mayri reared from L. coryli in Denmark; A. rusti reared from Pulvinaria sp., on sweet potato at Sullana, Piura. Peru; A. claviger collected at Auckland, New Zealand; A. eriococci reared from Eriococcus howardi on Quercus utahensis, Salt Lake City; and A. lutcolus reared from Coccus hesperidum, Saissetia olea, and C. citricola at various localities in California.

The genus Pseudococcobius is erected, and three species *Pseudococcobius* chrhorni reared from *Pseudococcus ryani* at San Francisco, Cal., *P. terryi* reared from *Pseudococcus saccharifolii* in Hawaii, and *P. bifasciatus* reared from *Phenacoccus* sp., on an apple tree at Lancaster, N. H., are also described as new.

The genus Bothriocræra is also erected and the type species B. flaripes reared from a dactylopiine coccid on Elymus at Kimballs, Utah, described as new.

Pseudaphycus graminicola reared from a dactylopiine coccid on stipa at Las Vegas, N. Mex., and Elymus condensatus at Kimballs, Utah; P. prosopidis reared from Pseudococcus prosopidis, Mesilla, N. Mex.; P. websteri reared from E. virginicus at Villa Ridge, Ill.; Acerophagus gutierreziæ reared from Pseudococcus gutierreziæ at Las Cruces, N. Mex.; A. erii reared from Erium lichtensioides at Salt Lake City, Utah; Aenasioidea tenuicornis reared from Kermes miyasakii at Akabane, Japan; A. kermicola reared from K. essigii on Quercus agrifolia, Pasadena, Cal., and from K. galliformis at Murray, Utah; and the genus Aphycopsis are described as new.

A contribution to a knowledge of Canadian ticks, C. G. Hewitt (*Proc. and Trans. Roy. Soc. Canada*, 3. ser., 9 (1915), Sect. IV, pp. 225-239, pls. 4).—This is a summary of knowledge of the occurrence, hosts, etc., of ticks in Canada in which 14 species and 1 variety are noted. A list of the literature referred to is appended.

Some centipedes and their venom, J. W. Cornwall (Indian Jour. Med. Research, 3 (1916), No. 3, pp. 541-557, pls. 5).—"The orifice of the venom duct is oval and lies on the dorsal surface of the venom claw, nearer the greater curvature and at a little distance from the apex. Centipedes possess four distinct pairs of glands with ducts opening near the head, namely, anterior salivary glands, posterior salivary glands, third pair of glands, and venom glands. Centipedes have definite ductless hæmopoietic organs. The toxic action of the venom is relatively low and is a character of secondary importance. The main function of the venom gland is probably to secrete digestive ferments, not to furnish a lethal agent. Extract of the salivary and the third glands contains lysins, which are selective, anticoagulin, diastase, invertase, and proteolytic enzyms."

#### FOODS-HUMAN NUTRITION.

Diet and dietetic therapeutics, C. A. EWALD and M. KLOTZ (Diät und Diätotherapie. Berlin: Urban & Schwarzenberg, 1915, 4. ed., pp. X+470, fig. 1).— While based on the third edition of Ewald and Munk's Nutrition of Man in Health and Disease (E. S. R., 8, p. 331) and designated in its subtitle as a fourth edition of that book, the present volume differs in many respects from the earlier. The general knowledge of the science of nutrition has progressed so far in the last 20 years that the discussions of the general functions of food and the stages in metabolism are no longer considered necessary in such a handbook for the general practitioner and consequently have been omitted by the authors. Where recent investigations have overthrown or extensively modified formerly accepted conclusions regarding specific subjects, more authoritative work has been substituted for that previously cited, but where recent work has simply confirmed older conclusions the sources utilized in the earlier editions have been retained. The sections dealing with the diet of infants and children both in health and disease are new, having been prepared by Klotz, who has also contributed the present section on milk.

Contributions to human nutrition (Zent. Einkaufsgesell. Beschränkt. Haftung, Abhandl. 1915, Orig., Nos. 1, pp. 73, figs. 4; 2, pp. 88, pls. 2, figs. 15; 1916. Nos. 3, pp. 78; 6, pp. 94, pls. 4, figs. 5).—This series of papers, in addition to summarizing data on various phases of human nutrition, reports some investigations carried on by the Central Purchasing Association, Ltd. The titles and authors of the publications follow: The Treatment and Utilization of Frozen Pork, by R. Plank and E. Kallert; Investigations Regarding Energy and Protein Requirements of the Higher Animals and Man, by H. P. Wamser (in which paper an attempt is made to express, by means of mathematical formulæ, the protein and energy requirements of different species, age, sex,

and activity); Preserved Meat and Preserved Sausage for the Nutrition of the Army and the Nation, by P. Koenig; and The Treatment and Utilization of Frozen Beef, by R. Plank and E. Kallert.

Circulars on human nutrition (Zent. Embautsgesell. Beschrautt Haftung, Flugschr. [1915], Orig., Nos. 2, pp. 15; 8, pp. 23; 9, pp. 16; 11, pp. 29, pgs. 4; 12, pp. 16; 13, pp. 12; 14, pp. 32; 15, pp. 16; 23, pp. 32; 6, 25, pp. 70; 7 This series of short popular articles deals with the economical use of food in the home. The titles and their authors follow: The Protein Supply of the German Empire, by H. P. Wamser; Sea Mussels as Food [Mythus eclulus and Mya arcnaria], by Ehrenbaum and F. Duge; Cookery with Little Fat. by Hedwig Heyl and N. Zuntz; Winter Vegetables as Human Food, by K. Weinhausen, Wilhelmine Tschernoglasow, and M. Rubner; Potato Cookery in Wartime, by Josephine Nagel and E. Abderhalden; Christmas Faking in Wartime; Short Contributions to Human Nutrition (collected articles from hroughout); Cured Fish as Human Food and its Utilization in Minced and Saussee Form, by C. Kallert and Johanna Martin; Our Wild Plants in Cookery, by R. Winchel; and War Cookery in the Summer of 1916. Recipes for Rations Poor in Meat and Fat, by Josephine Nagel and C. Oppenhelmer.

The shortage in the fat supply, its cause, and means of remedy, E. Mattell. (Rev. Hyg. ct Pol. Sanit., 38 (1916), No. 7, pp. 642-672). The author discusses the fat requirements of France, the sources of supply, the causes of the diminution of production and increase in cost, and apprepriate measures for avoiding a deficiency in the supply of fat (thereby avoiding the increase in price). The fat requirements of the individual are placed at 1 gm. per kilogram of body weight; that is, 65 gm. for the average adult. Of this about 35 gm. is caten as a constituent part of the average food and 30 gm. as added fat. The actual supply of fat in the Republic is held to be quite sufficient for the needs of the inhabitants.

Bacteriological analysis of oysters sold at Marseille, A. Groon and C. Richet, Jr. (Rev. Hyg. et Pol. Sanit., 38 (1916), No. 7, pp. 621-641, fig. 1).—Bacteriological examination of the oysters sold in Marseille showed them to be badly contaminated. High bacterial contents, with a large percentage of Bacillus coli, were found in the case of the shell liquor and the intestinal mass. The organisms of typhoid and paratyphoid A and B were also isolated. The waters from which the oysters were taken and those in which they were floated were badly polluted with sewage. Recommendations are formulated for improving the sanitary quality of the oysters.

Milling and baking, L. Ammann (Meuneric et Boulangerie. Paris: J. B. book of milling and baking. Information is given regarding the different varieties of wheat and their composition and food value. The methods employed and the apparatus used in cleaning and milling wheat are described in detail. Information is also given regarding the preparation of doughs and baking.

Making light bread, Addle D. Root (Univ. Missouri, Coi. Agr. Est. Serv. Circ. 11 (1916), pp. 11).—A popular bulletin which gives information regarding the ingredients used and their proportions, the handling of the ingredients, and bread diseases.

Rice, as prepared for food in Bengal, J. N. RAKSHIT (Agri. Jour. India, 11 (1916), No. 2, pp. 174-198).—This article describes in detail the method of preparation, properties, and uses of a number of native dishes prepared from both the unhusked and husked rice.

Breakfast foods and their relative value, G. E. YOUNGBURG (South Dakota Sta. Bul. 168 (1916), pp. 447-461).—Analytical and cost data are given regarding a number of breakfast foods sold in the State. The retail price per pound

varied from 7.2 to 43.9 cents. It is stated that with care in selection a saving of from 30 to 100 per cent may be made. The nutritive value per pound of the different foods did not vary materially.

Sanitary studies of baking powders.—Is aluminum absorbable from bread, and similar food products, made with alum baking powder? W. J. Gies (Biochem. Bul., 5 (1916), No. 20-21, pp. 151-157).—The author refers to the apparent disagreement in the results of previous work by himself and colleagues (E. S. R., 26, p. 564) on the effect of aluminum salts and the findings of the Referee Board of Consulting Scientific Experts of the U. S. Department of Agriculture on the question of alum in baking powder (E. S. R., 31, p. 556). He presents an outline of a further study of this question, to be carried out with the independent cooperation of other investigators. This is to include a study of analytical methods (noted on page 802 of this issue), an investigation of the facts pertaining to the observation and examination of aluminum salts in the case of human subjects, and a repetition of a portion of his earlier experiments with laboratory animals (dogs).

The bacteriology of the bubble fountain, DOROTHY F. PETTIBONE, F. B. BOGART, and P. F. CLARK (Jour. Bact., 1 (1916), No. 5, pp. 471-480, fig. 1).—The investigation here reported was made as the result of an epidemic of streptococcus tonsilitis, in which bubble fountains were suspected to be a factor in transmitting the disease. The city water was found to be free from streptococci.

"A survey of all the fountains of the University [of Wisconsin] showed the presence of streptococci in over 50 per cent of the total number. The streptococci varied in abundance from a few chains to an almost pure culture obtained by swabbings from the fountains in the women's dormitory.

"In an experimental bubble fountain, *Bacillus prodigiosus* when introduced either by means of a pipette or by the moistened lips remained in the water from 2 to 135 minutes, depending partly on the height of the 'bubble.'

"Most of the organisms are flushed away, but some remain, dancing in the column much as a ball dances on the garden fountain, even though the bubble be increased to the impractical height of 4 in.

"To avoid the difficulty always present in the vertical column, a simple fountain with a tube at an angle of 50 degrees from the vertical was constructed. B. prodigiosus was never found in the plates from this type of fountain, even when samples were taken immediately after the introduction of the organism. . . . [It is believed] that this type of fountain should be generally adopted. Its simplicity, low cost of construction, and freedom from lurking danger should recommend it to all."

Court decision pertaining to the public health [including foods] (Pub.  $Health\ Rpts$ . [ $U.\ S.$ ],  $Reprint\ 342\ (1913-1916)$ ,  $pp.\ XXV+192$ ).—This is a compilation of judicial opinions which have been published in public health reports between May 30, 1913, and July 14, 1916. Several of these opinions have to do with pure-food laws and food sanitation.

Report of the Bureau of Markets of the City of Newton, Mass. (Rpt. Bur. Markets [Newton, Mass.], 1915, pp. 56, pls. 2, figs. 10).—In addition to presenting a review of the work of the bureau for the three months ended December 31, 1915, this report discusses the underlying causes of high food costs and gives a comparison of prices of produce sold in the public markets and in the retail stores of Newton and in other places.

Retail prices of food supplies in New Jersey (Ann. Rpt. Bur. Indus. Statis. N. J., 38 (1915), pp. 149-157).—This is a compilation of the retail prices of a selected list of food supplies prevailing during the month of June, 1915, as reported by representative dealers in the principal centers of population of the State.

Cost of food for an adult woman, Miss C. E. Collet (Jour. Roy. Statis. Soc., 79 (1916), No. 3, pp. 300-308).—The data presented in this paper show the average cost of food per person per week in households of adult women (in all of which some one was especially in charge of the housekeeping) and for adult wage-earning women having no one at home in charge of the housekeeping. The paper is followed by a discussion.

The cold school lunch, BAB BELL (Univ. Missouri, Col. Agr. Ext. Serv. Circ. 10 (1916), pp. 8, figs. 3).—Suggestions are given for the choice of foods, the selection of the container, and the packing of the lunch.

Restricted diet and nutritional deficiency, E. Weill, G. Mouriquand, and P. Michel (Compt. Rend. Soc. Biol. [Paris], 79 (1916), Nos. 2, pp. 37-39; 5, pp. 189-199; 9, pp. 382-386),—The authors state that the term "restricted diet" may have different meanings, some restricted diets permitting of normal nutrition while others result in illness and, in some cases, in death. In their opinion deficiency diseases are due to depriving the food of some essential substances (vitamins) either by removing the outer coats of cereals or by sterilization of the food.

Experiments with laboratory animals (cats) are reported which showed that diets of raw, frozen, or salted meat did not produce symptoms of nervous degeneration due to deficiency of the diet. Cats fed exclusively upon sterilized meat showed symptoms similar to those produced in pigeons fed upon exclusive diets of cereals which had been sterilized or those from which the outer layers had been removed.

It is the authors' belief that sterilization in the case of meat or grains removes some ferment which is essential to normal nutrition of the body, especially the nutrition of the nervous system. Pigeons which were fed exclusively upon a diet of raw polished rice showed nervous degeneration due to the dietary deficiency. Sterilization of the grains produced the same effect as a removal of the outer coat, and sterilization of the grains after the removal of the outer coat hastened the appearance of the symptoms in the case of pigeons.

The importance of vitamins in relation to nutrition in health and disease, C. Voegetlin (Jour. Wash. Acad. Sci., 6 (1916), No. 16, pp. 575-595).—In this lecture the author outlines briefly recent advances in the science of nutrition, especially with reference to the importance of the presence in the diet of small quantities of substances essential for the maintenance of health. The subjects considered are the deficiency disease, beri-beri; the isolation and chemical properties of vitamins; the physiological action of vitamins; and the distribution of vitamins in foods. A discussion of the factors which tend to reduce the vitamin content of the diet is included.

The digestibility and utilization of egg proteins, W. B. BATEMAN (Jour. Biol. Chem., 26 (1916), No. 1, pp. 263-291).—The author reports the results of an extended study of the behavior of egg white in the alimentary tract by means of experiments with laboratory animals (dogs, rats, and rabbits) and human subjects. The data reported may be summarized as follows:

"Raw egg white is found to be a decidedly indigestible substance. It may cause diarrhea in dogs, rats, rabbits, and man when ingested in any large quantity. Its utilization by the body is poor since it is used only to the extent of from 50 to 70 per cent. Subjects can acquire a certain tolerance for the native protein after ingesting it for several days so that it no longer causes diarrhea and is somewhat better utilized."

It was found that raw egg white could be made digestible through coagulation by heat; by precipitation with alcohol, chloroform, and ether; by incubation with dilute acids or alkalis; by partial digestion by pepsin; or by conversion into alkali-metaprotein. The well-cooked whites of from four to

six eggs could be eaten by dogs without the production of any of the symptoms resulting from the ingestion of the raw egg white. About 90 per cent of the nitrogen in cooked eggs was utilized as compared with 50 to 70 per cent in the case of the raw egg white.

"The indigestibility of native egg white probably lies either in its antitryptic content or in its chemical constitution. Its physical texture appears to play a minor part in its behavior.

"Of the individual proteins constituting egg white, the albumin fraction appears to be the indigestible component.

"The whites of the hen's egg and duck's egg act alike in causing diarrhea and in being poorly utilized.

"Egg yolk either raw or cooked is excellently utilized. It sometimes causes digestive disturbances in dogs, apparently because of its high fat content."

The author states that the observations of earlier investigators, relied upon by dietitians in supporting the use of raw eggs, have been misinterpreted and that while raw whole eggs, raw egg white, and albumin water are excessively prescribed in dieto-therapy there is little basis of fact for this practice, in view of the data obtained in this investigation.

An extended bibliography is appended.

Feeding experiments on the substitution of protein by definite mixtures of isolated amino acids, H. H. MITCHELL (Jour. Biol. Chem., 26 (1916), No. 1, pp. 231-261, figs. 5).—Experimental data obtained by other investigators on the feeding of mixtures of amino acids to the exclusion of protein are reviewed at length, and the author reports experiments undertaken for the purpose of discovering some mixture of isolated amino acids which would be capable of supporting life. Although the results of these experiments have not been entirely successful, they have several points of interest. The results of the investigation may be summarized as follows:

Mice were kept alive for from 70 to 98 days by feeding alternately a ration containing from 4 to 6 per cent of various mixtures of isolated amino acids, 6 to 4 per cent sucrose, 34 per cent starch, 28 per cent protein-free milk, 10 per cent lard, and 18 per cent butter fat, and a ration containing 10 per cent of sucrose with other constituents in the same proportion as the first. In some of the experiments the mice practically maintained their weight for periods of from 15 to 35 days.

"The alternate feeding of an amino acid ration and a nonnitrogenous ration (except for the nitrogen present in the protein-free milk) induced a better total consumption of food than feeding with an amino acid ration alone, and in all other respects led to more successful results. However, it is probable that in no case was the amino acid intake sufficiently large to assure a fair test of its adequacy.

"Amino acid rations containing no added tyrosin, or no added tyrosin and phenylalanin, did not give appreciably different results from rations containing these amino acids. However, if tryptophane was absent from an amino acid ration the period of survival of mice fed this ration alternately with the nonnitrogenous ration was noticeably shorter than the periods of survival of mice kept on rations containing added trytophane.

"Mice could be kept for much longer periods of time on rations containing mixtures of amino acids, including trytophane and fed alternately with the non-nitrogenous basal ration, than when fed the basal ration alone. Furthermore, this difference in survival can not be accounted for by a difference in energy intake. This fact has been interpreted as meaning that at least some of the amino acids have specific functions in metabolism aside from that of serving simply as material for the synthesis of body protein."

This view is supported by the results of other investigators cited from the literature.

The influence of ingested carbohydrate, protein, and fat on the blood sugar in phlorizin diabetes, F. A. CSONKA (Jour. Biol. Chem., 26 (1916), No. 1, pp. 93-98, flg. 1).—Following the ingestion of 20 gm. of glucose by phlorizinized laboratory animals (dogs) the blood sugar reached the maximum at the second hour and declined to the original level at the fourth hour. It was found in earlier experiments (E. S. R., 33, p. 755) that 94 per cent of 16 gm. of glucose given to a phlorizinized dog was excreted during the first five hours as "extra glucose."

As the elimination of the ingested glucose was practically complete and the curve of blood sugar was parallel to that of extra glucose, the conclusion is drawn that no glucose was deposited between the periods of absorption and elimination.

"That the blood sugar is increased after ingestion of protein is apparent from the curve which shows that the endogenous glucose derived from meat protein and gelatin appears in the blood as glucose—at least, partially so—since the isoglucogenic quantities of ingested endogenous and exogenous glucose should give the same increase of blood sugar. The ingestion of fat, which does not produce 'extra glucose,' did not cause any appreciable increase in blood sugar."

Studies of urinary and blood nitrogen curves after feeding in the dog, O. H. P. Pepper and J. H. Austin (*Proc. Soc. Expt. Biol. and Med., 12* (1915), No. 8, pp. 179-181).—The daily variation in the nonprotein blood nitrogen in a normal dog receiving a diet containing 0.4 gm. of nitrogen per kilogram of body weight was about 9 mg. The maximum was reached about 2 hours after feeding, and the original level was reached in about 10 to 14 hours. The feeding of excessive quantities of meat increased the nonprotein blood nitrogen from 25 to 40 mg. in from 6 to 8 hours and the original level was not reached at the end of 24 hours. The curve of nonprotein blood nitrogen in a normal dog after feeding followed closely the curve of the urinary nitrogen.

"In the fasting dog there occurs a gradual fall in blood nitrogen to a minimum of from 12 to 18 mg., reached in from 30 to 48 hours after the last feeding, and followed by a rise in the next few hours to about 25 mg., at about which level it tends to persist. The urinary nitrogen shows a similar but less pronounced curve."

The elimination of ammonia in the urine during rest, D. Liotta (Arch. Farmacol. Sper. e Sci. Aff., 22 (1916), No. 6, pp. 205-228, figs 5).—Experiments are reported with laboratory animals (dogs) and human beings, which show that the elimination of ammonia in the urine increased notably during rest.

The metabolism of sulphur.—I, The relative eliminations of sulphur and nitrogen in the dog in inanition and subsequent feeding, H. B. Lewis (Jour. Biol. Chem., 26 (1916), No. 1, pp. 61-68).—The author reviews critically the work of other investigators on the excretion of sulphur as related to nitrogen elimination and reports the results of his own experiments on this subject. In the case of laboratory animals (dogs), determinations were made of the nitrogen and sulphur elimination during periods of prolonged fasting and during subsequent shorter periods of alternate fasting and feeding.

The experimental data showed no evidence of any increasing retention of sulphur as compared with nitrogen. The nitrogen: sulphur ratio during the fasting periods, with two exceptions, varied within narrow limits (from 14 to 15 for the most part).

The author states that if a partial conservation of the protein molecule in cellular catabolism can be effected by the organism, as has been suggested by

other investigators, this does not appear to be effective in the case of the sulphur fraction of the molecule in the light of these experiments. "This conclusion is in accord with the present-day conception of the indispensability of adequate amounts of preformed cystin in the diet, as recently exemplified by the experiments of Osborne and Mendel on white rats."

High nitrogen: sulphur ratios, with a retention of sulphur, were found during the feeding periods following the fasting periods. When the feeding periods extended over a number of days there occurred a gradual diminution of the ratio to normal, but if the feeding period was followed by a fasting period the ratios were lower than the normal or fasting ratios, indicating an excessive elimination of sulphur as compared with nitrogen. On the basis of unpublished experimental data, the author believes that this indicates a retention of sulphur to build up sulphur-rich tissues, as the result of a specific attempt of the organism to restore material lost during the starvation period, rather than a lag in the elimination of sulphur.

## ANIMAL PRODUCTION.

Experimental studies on growth, II-VII, T. B. ROBERTSON, L. A. RAY, and ETHEL CUTLER (Jour. Biol. Chem., 24 (1916), No. 3, pp. 363-408, figs. 14; 25 (1916), No. 3, pp. 635-667, figs. 13).—In continuation of work already noted (E. S. R., 35, p. 65), six papers are here presented on the influence of protein dietary factors upon the process of growth and phenomena incident thereto in white mice.

II. The normal growth of the white mouse (pp. 363-383).—In these studies it was found that "in each sex there are three separate extra-uterine growth cycles. The first cycle attains its maximum velocity at some time shortly prior to 7 days after birth and culminates at 14 days. The second cycle attains its maximum velocity at from 21 to 23 days and culminates soon after the twenty-eighth day. The third cycle attains its maximum velocity at about 6 weeks and thereafter decreases in velocity continuously but very slowly, so that growth of the animals still occurs between the fiftieth and sixtieth weeks succeeding birth.

"All the cycles are less extensive in the female than in the male.

"The variability in weight of the animals shows a decided tendency to increase with increasing velocity of growth and to decrease with decreasing velocity of growth. After the fortieth week, however, especially in the females, there is a tendency of the variability to increase progressively without any corresponding increase in the rate of growth.

"Weaning of the animals on the twenty-first day after birth produces no physiological disturbance whatever in the young.

"It is shown from the variability of the weight that considerable numbers of animals must be employed to obtain reliable data in experiments upon growth. The weight data reported in this and succeeding articles are probably within 1 or 2 per cent of the true values.

"Birth in mice occurs during the first half of the first growth cycle. The eyes open coincidently with the culmination of the first growth cycle, a complete coat of fur being acquired at the same time. Puberty coincides with the period of maximum velocity of growth due to the third growth cycle.

"The development of the thyroid and of the thymus in mice presents well-marked stages which coincide closely with the cycles displayed in the growth curve of these animals. Subsequent to the culmination of the first-growth cycle the thyroid is heavier in the male than in the female, while the thymus is heavier in the female than in the male.

"There is a steady decrease in the percentage content of alcohol-soluble phosphorus in the tissues (other than cerebral tissues) of mice from birth to 210 days of age, and this decrease is almost exactly in direct proportion to their age."

III. The influence of the anterior lobe of the pituitary body upon the growth of the white mouse (pp. 385–396).—It was found that "the administration of 0.125 gm. per day per animal of fresh anterior lobe pituitary tissue to mice, beginning at 4 weeks after birth (conclusion of the second growth cycle) leads to retardation of growth during the earlier portion of the third-growth cycle, between the sixth and twentieth weeks. In the latter part of the third-growth cycle, however, from the twentieth to the sixtieth weeks after birth, the growth of the pituitary-fed animals is markedly accelerated, so that they not only catch up to the normals, but actually, at about one year of age, come to surpass the normals in weight.

"The effect of the pituitary tissue upon the variability of the weight of the animals is similar to its effect upon the velocity of their growth. The variability is diminished in the earlier portion of the third-growth cycle, particularly between the tenth and the twentieth weeks. Between the twentieth and the sixtieth weeks, however, the variability curves of the pituitary-fed animals approach the variability curves of the normals, and at about the fortieth or fiftieth week the two variability curves intersect.

"Pituitary-fed animals, from about the thirtieth week onward, appear more compactly built than normal animals. The pituitary-fed animals, weight for weight, are smaller than the normals of the same age, and size for size they are heavier. Pituitary-fed males are noticeably more belligerent in their habits than normal males."

IV. The influence of tethelin, the growth-controlling principle of the anterior lobe of the pituitary body, upon the growth of the white mouse (pp. 397-408).— From the concentrated alcoholic extract of dried anterior lobes of ox pituitaries a substance has been extracted and named tethelin.

"The effects of tethelin upon the growth of white mice resemble in every particular the effects of the administration of the whole anterior lobe. These effects consist in marked retardation of the first portion of the third growth cycle followed by acceleration of the latter portion of the third growth cycle. The variability in weight of the tethelin-fed animals, like that of the pituitaryfed animals, is less than that of normals of the same age. Adult tethelin-fed animals, like adult animals which have been fed upon the anterior lobe of the pituitary body, are more compact in form and build than normal animals of the same age. Weight for weight the tethelin-fed animals are smaller than the normal ones, and size for size they are heavier. The coats of adult male animals which have been fed with tethelin retain, even at 14 months of age. the glossy silky appearance of the coats of young animals. Normal males, even 6 months prior to this age, have shaggy, staring, and discolored coats. This improvement in the coat was not observed in the pituitary-fed animal. Tethelinfed animals do not display the remarkably enhanced belligerency which is exhibited by pituitary-fed animals."

V. The influence of cholesterol upon the growth of the white mouse (pp. 635-646).—It was found in these studies that "the administration of 40 mg, per day per animal of cholesterol to mice, beginning at five weeks after birth (conclusion of the second growth cycle), leads to marked retardation of growth during the earlier portion of the third growth cycle, between the fifth and tenth weeks. From the tenth week onward, however, growth is decidedly accelerated, although the acceleration is insufficient to compensate entirely for the initial retardation. The influence of cholesterol upon the third growth cycle in mice is

therefore comparable with that produced by the administration of much smaller doses of tethelin. The influence of cholesterol upon the variability of the animals to which it is fed is, however, directly opposite to the effect exerted by tethelin, for while tethelin reduces the variability of the animals to which it is fed, cholesterol increases their variability. This increase in variability is mainly attributable to the very unequal acceleration, in different individuals, of the latter portion of the third growth cycle.

"Cholesterol-fed animals do not noticeably differ in build from normal animals. Their coats are smoother and more glossy in appearance than those of normal animals of the same age. Between the fifth and tenth weeks the testicles of cholesterol-fed males become very prominent. This disproportion between the size of the testicles and that of the animals bearing them rapidly disappears subsequent to the tenth week. It is probably due to absence of retardation of the growth of the testicles during the first five weeks of feeding, so that the retardation of the body growth of the animals leads to disproportionate size of the testicles. The subsequent acceleration of the body growth restores the normal proportion.

"No deleterious effects attributable to the feeding of cholesterol were observed. Three animals which were examined after 50, 463, and 511 days of feeding, respectively, showed no evidence of lesions in the wall of the aorta such as are observed in rabbits after feeding relatively smaller doses for comparatively brief periods of time."

VI. The influence of lecithin upon the growth of the white mouse (pp. 647-661).—In these studies it was found that "the administration by mouth of 80 mg. per day per animal of egg lecithin, beginning at four weeks after birth (conclusion of the second growth cycle), leads to no deformation of the curve of growth, the only demonstrable effects of the administration consisting in a very slight uniform retardation of growth and a low degree of resistance to infection, both effects being not improbably attributable to the injurious action of excess of cholin absorbed from the alimentary tract.

"The administration by mouth of 4 mg. per day of lecithin derived from the anterior lobe of the pituitary body produces similar effects. Having regard to the comparatively small dose administered it is possible that these effects may in part have been due to admixture of other and more potent substances with lecithin derived from this source, or at all events to a peculiarity of lecithin derived from the anterior lobe of the pituitary body.

"The lack of effect of lecithin administered by mouth in comparison with its effects when administered subcutaneously or to lower organisms is probably attributable to the fact that lecithin is completely split during digestion and is not absorbed to any appreciable extent as such."

VII. The influence of the administration of egg lecithin and of cholesterol to the mother, upon the growth of suckling mice (pp. 663-667).—The authors found in these trials that "the administration of 100 mg. of egg lecithin per day by mouth to the mother slightly retards the growth of suckling mice. The administration of 100 mg. of cholesterol per day by mouth to the mother causes a very marked retardation of the growth of suckling mice between the ninth and twenty-first days after birth."

It is not decided "whether these actions represent the direct effect of lecithin and cholesterol upon the growth of sucklings or only an indirect effect due to interference with the supply of milk."

The mechanism of crossing-over, I, II, III, IV, H. J. MÜLLER (Amer. Nat., 50 (1916), Nos. 592, pp. 193-221, figs. 5; 593, pp. 284-305, figs. 4; 594, pp. 350-366; 595, pp. 421-434, figs. 4).—The author summarizes the results of his studies as follows:

"Recent results complete the parallelism between factor groups and chromosomes in Drosophila. This strengthens the evidence that separation of linked factors is due to an interchange between chromosomes.

"The chief gaps in the information regarding the total frequency of interchange in the different groups have been filled, and it is found that the usual total frequencies of separation correspond to the lengths of the chromosomes. This constitutes specific evidence that crossing-over is the method of interchange between the chromosomes, and that the frequency of crossing-over between factors is determined by their distance apart in the chromosome. It supplements the other evidence for these conclusions that had previously been found by Sturtevant in the linear manner of linkage of the factors.

"It seems uncertain whether crossing-over occurs in the strepsinema stage, as concluded by Janssens, or earlier in synapsis. The cytological evidence at present at hand would seem insufficient to settle this point. Possible tests for various alternative mechanisms of crossing-over are proposed.

"In order to study the nature of crossing-over by means of 'interference' stocks were made up that differed in regard to many factors. Females beterozygous for 22 pairs of factors were thus obtained, and a special method was devised for testing their output. Other special methods for obtaining multiple stocks and for eliminating discrepancies due to differential viability have also been presented. The results have been arranged in the form of a curve showing the amount of interference for various distances. The results thus far obtained confirm those obtained by less exact methods, and also give evidence that interference decreases gradually with distance from a point of crossing-over; this, taken together with certain evidence from nondisjunction, lends some probability to the view that crossing-over occurs at an early stage in synapsis.

"A case of crossing-over in an embryonic cell of a male is reported.

"Incidentally, the experiments have afforded an extensive test of Castle's assumption of contamination of factors by their allelomorphs. Outcrossing in each generation for 75 generations has failed to change any of the factors."

A bibliography of references is included.

Investigation in Mendelian inheritance, G. Lefevre and E. H. Rucker (Missouri Sta. Bul. 141 (1916), p. 42).—A progress report of work in crossing Silver-Spangled Hamburg × Brown Leghorn, and Sebright × Rose-Comb Black Bantam. In the latter cross the F₂ cocks showed three conditions: (1) Malefeathered (SS); (2) hen-feathered (ss); and (3) intermediate condition (Ss).

Total, digestible, and manurial composition and compensation value of foodstuffs, compiled by G. S. Robertson (Chelmsford, England: East Anglian Inst. Agr. [1916], pp. 25).—Compiled analyses are given of a large number of feeding stuffs and similar materials.

Studies on the mineral elements in animal nutrition, E. B. Forbes (Jour. Wash. Acad. Sci., 6 (1916), No. 13, pp. 431-446).—The author summarizes the results of metabolism experiments conducted at the Ohio Experiment Station and previously reported from various sources.

Inspection of feeding stuffs (New York State Sta. Bul. 420 (1916), pp. 161-309).—Analyses of the following feeding stuffs are given: Cotton-seed meal; linseed meal; malt sprouts; distillers' and brewers' dried grains; yeast or vinegar dried grains; corn gluten feed and meal; hominy feed; meat scrap and beef scrap; fish scrap; tankage; bone meal; red dog flour; wheat bran and middlings; rye bran and middlings; buckwheat bran and middlings; barley middlings; corn, pea, coconut, and alfalfa meals, corn oil cake meal, and peanut oil meal; dried beet pulp; oat hulls; and various mixed and proprietary feeds.

The grazing industry of the blue grass region, L. CARRIER (U. S. Dept. Agr. Bul. 397 (1916), pp. 18, figs. 16).—This bulletin gives a general review of the

grazing industry of the blue grass regions of Virginia, North Carolina, Tennessee, Kentucky, and West Virginia, the topics dealt with being the different grades of blue grass pastures, effect of winter grazing on the sod, kinds of live stock raised, wintering the steers, getting a sod, value of a pasture when grazed with cattle and with sheep, maintaining the fertility of the soil, the proper rate to graze, care of pastures, and the supply of stockers.

In estimating the value of blue grass pasture when grazed with cattle, data were collected from 22 pastures in Virginia, West Virginia, and Kentucky, averaging 193 acres and 60.4 head of cattle. The average results obtained were as follows: Yearly gain per steer 386 lbs., and per acre, 121 lbs.; gross returns, \$12.40 per acre; cost of wintering per steer \$12.13, and per acre of pasture, \$3.80; and net returns, \$8.60 per acre. The acreage of pasture per steer varied from 5.55 to 1.8; the yearly gain per acre from 68 to 222 lbs.; the cost of wintering from \$30.83 to \$7.50 per steer; and the net returns per acre from \$2.10 to \$14.08. The values assigned in obtaining these results were 7 cts. per pound as the purchase price of stockers, 8 cts. as the selling price, \$4 a ton for silage, 60 cts. a bushel for corn, \$12 a ton for hay, \$6 a ton for corn stover, and \$4 a ton for straw. Taxes, insurance, fencing, and labor of caring for stock were not included.

Data on pasturing sheep on six pastures show that the annual returns per acre of pasture, with wool at 25 cts. per pound and lambs at 7 cts. per pound, varied from \$2.90 to \$12.66. The author states that the average cost of wintering sheep is about 75 cts. per head.

[Animal husbandry], Missouri Sta. Bul. 141 (1916), pp. 19-25, figs. 5).—Notes on the following investigations, continuing work previously noted (E. S. R., 33, p. 265), are presented:

Use of feed experiment, by P. F. Trowbridge, C. R. Moulton, and L. D. Haigh.—In this experiment it was found that heifers grown on a low plane of nutrition seem to produce as well-fleshed calves as those grown on a higher plane of nutrition.

A thrifty yearling steer has a strong tendency to grow. One that gained only 0.5 lb. a day became thinner in flesh. At the end of a year on such a plane of nutrition he had less tendency to grow and an increased tendency to put on fat. A thrifty yearling steer kept at body maintenance weight for a year made a marked skeletal growth and used most of his reserve tissue fat but none of the fat stored in the skeleton. Another such steer continued to grow when made to lose 0.5 lb. a day, but the fat from the skeleton as well as the tissue fat was consumed during a year of such treatment. The composition of a thin 3-year-old steer is given as water 56.4 per cent, protein 18.85, fat 18.59, and ash 5.72; of the first 500 lbs. gain made, water 37.58, protein 11.92, fat 48.56, and ash 1.96; and of the second 500 lbs. gain made, water 17.77, protein 5.15, fat 75.88, and ash 1.5. Measurements indicate that such an animal makes a marked skeletal growth during the period of fattening.

Factors influencing the normal rate of growth in domestic animals and the permanency of the effects of arrested development, by F. B. Mumford and P. F. Trowbridge.—Beef calves are the subject of this experiment, which has been in progress only a short time. It has not been difficult to hold the animals in the low plane of nutrition group to the required rate of growth on a roughage ration of alfalfa hay and oat straw, 3:2.

Age as a factor in animal breeding, by F. B. Mumford and L. A. Weaver.— Observations have been made on 615 pigs of sows of three groups, immature, half-mature, and mature. The pigs from very young mothers are apparently somewhat less vigorous and smaller at birth than the pigs from the older sows. The first period of lactation in the very young sows exerts a markedly retarding effect on the growth of the mothers. These results confirm last year's work (E. S. R., 33, p. 265).

A study of the residual effects of forage crops for swine, by L. A. Weaver.—
The results of this year's trials were the reverse of those obtained last year
(E. S. R., 33, p. 266). This year there was found to be a slight advantage in
favor of pigs which had previously been in dry lot, as compared with those
previously on pasture. From the results of the two years' investigation
there is little evidence that hogs fed on forage crops during the summer are
more quickly or economically fattened after such treatment than similar hogs
fed in a dry lot during the same period.

Forage crops for pork production, by L. A. Weaver.—The results of this experiment indicate that it is not necessary to supplement a corn ration with tankage, or other high protein food, when hogs are on rape pasture. Results of other tests indicate that it is a profitable practice to feed a small amount of tankage to hogs pastured on corn and cowpeas.

Corn silage as a part ration for horses of various ages, by E. A. Trowbridge and E. H. Hughes.—The animals studied included draft horses and mules, saddle mares, draft and saddle foals, 2-year-old fillies, and 3-year-old geldings, divided into pairs. Each animal received the same grain ration consisting of corn, oats, and bran, 2:2:1. One of the animals in each pair of the growing and idle horses received alfalfa hay as its roughage, part of which was fed at night and part in the morning. The other animal in each pair received alfalfa hay in the morning and corn silage at night. The draft animals at work were fed the same except that timothy hay was used instead of alfalfa. Some difficulty was experienced in getting the animals that had been on dry feed previous to the test to eat the silage.

With two exceptions, the animals receiving silage were in a more thrifty condition at the end of the trial. The results of the first test indicate that silage can be successfully substituted for a part of the hay in the ration of horses at the rate of 2 lbs. of silage for 1 lb. of hay.

[Animal husbandry], A. C. Hartenbower and L. B. Barber (Guam Sta. Rpt. 1915, pp. 15, 16, 22-25, pl. 1).—The breeding experiments with horses, cattle, pigs, goats, and chickens have been continued along the same lines as heretofore (E. S. R., 32, p. 767). It has been uniformly noted that the station's purebred sires bring about a marked improvement in the native live stock even in the first generation, although from the standpoint of hardiness a certain percentage of native blood appears to be desirable. The effect of inbreeding has become strongly noticeable in the station's pigs and chickens, and arrangements have been made for the shipment of pigs, goats, and chickens from the United States to the station. In an effort to improve live stock on the island the station has made arrangements to send breeding sires to different sections.

In a preliminary test of pasture crops for pigs cowpeas proved superior to soy beans. Results indicated that in wet seasons at least two crops of pasture can be secured from one sowing of cowpeas. The cowpeas and soy beans were seeded in December. One-half an acre of Para grass kept six sows and one boar in good flesh throughout most of the extreme dry season. This test showed that Para grass should not be pastured too heavily, and that it should be given rest periods of two out of every five weeks to recuperate.

In a feeding test with pigs a ration of native feeds was compared with a ration of imported feeds. Two lots of 4 Berkshire-native cross-bred pigs were used in the experiment which lasted 64 days. Each lot received 10 lbs. of Para grass daily, and in addition one lot was fed 18 lbs. of breadfruit and 3 lbs. of

grated coconut daily, and the other lot 4 lbs. of corn chop and 4 lbs. of wheat shorts daily. The first lot made an average daily gain of 0.44 lb. per pig at a cost of 10.1 cts. per pound of gain. The second lot made an average daily gain of 0.52 lb. per pig at a cost of 9.5 cts. per pound of gain. Breadfruit was valued at 0.5 ct. per pound, grated coconut at 1 ct. per pound, corn chop at 2.25 cts. per pound, and wheat shorts at 1.75 cts. per pound.

[Calf and pig feeding experiments], J. M. Scott (Florida Sta. Rpt. 1915, pp. XXI-XXIV).—Three lots of four grade Jersey heifer calves each were fed 35 days as follows: Lot 1, 4 qt. of whole milk per calf per day; lot 2, 4 qt. of whole milk and 12 oz. of oatmeal per calf per day; lot 3, 8 qt. of whole milk per calf per day. Each lot of calves had 0.1 acre of Dwarf Essex rape pasture. The calves made average daily gains per head of 0.457, 1.04, and 1.65 lbs. for the respective lots.

A pig feeding test with dasheens is noted below.

Pig feeding, J. M. Scott (Florida Sta. Bul. 131 (1916), pp. 59-69, fig. 1).—This is a continuation of work previously noted (E. S. R., 28, p. 770).

Two lots of four 75-lb. Berkshire pigs each were fed 46 days, lot 1 receiving shelled corn and green cowpeas, and lot 2, shelled corn and green sorghum. The shelled corn and green feed were fed in equal amounts, and each lot of hogs received the same number of pounds of feed. These pigs made average daily gains per head of 0.43 and 0.36 lb., and consumed per pound of gain 11.7 and 14 lbs. of feed for the respective lots.

Three lots of pigs were fed 43 days as follows: Lot 1, shelled corn; lot 2, shelled corn and peanuts, 3:1; lot 3, shelled corn and peanuts, 1:1. All lots were fed Dwarf Essex rape in addition to the other feeds. These pigs made average daily gains per head of 0.686, 0.72, and 0.774 lb., consuming per pound of gain 4.67, 4.44, and 4.14 lbs. of feed for the respective lots. The hogs that were fed peanuts presented a better appearance than those fed corn and rape only. Their coats were much smoother, and they were more thrifty generally.

Three lots of 5 pigs each were fed 31 days as follows: Lot 1, shelled corn; lot 2, shelled corn and ground velvet beans, 3:1; and lot 3, shelled corn and ground velvet beans, 1:1; all lots being fed Dwarf Essex rape in addition to the other feeds. These pigs made average daily gains per head of 0.31, 0.23, and 0.2 lb., consuming per pound of gain 18.3, 24.5, and 28 lbs. of feed for the respective lots.

Five lots of 4 pigs each were fed 30 days as follows: Lot 1, corn alone; lot 2, corn and cracked velvet beans, 3:1; lot 3, corn and cracked velvet beans, 1:1; lot 4, corn and cracked velvet beans, 1:1, plus iron sulphate; and lot 5, corn and cracked velvet beans, 3:1, plus iron sulphate. The iron sulphate was used in an attempt to improve the velvet-bean ration, since previous results had been unsatisfactory. This salt has been used successfully with cotton-seed meal, but results of this test did not indicate that iron sulphate was beneficial in producing gains. These pigs made average daily gains per head of 0.47, 0.63, 0.56, 0.52, and 0.53 lb., consuming per pound of gain 6.35, 4.8, 5.37, 5.74, and 5.62 lbs. of feed for the respective lots.

Four lots of pigs were fed 59 days as follows: Lot 1, shelled corn alone; lot 2, shelled corn and raw dasheens, 1:4; lot 3, shelled corn and raw dasheens, 1:1; and lot 4, shelled corn and dasheens, 1:4, and a small amount of velvetbean meal. These pigs made average daily gains per head of 0.45, 0.107, 0.38, and 0.187 lb., consuming per pound of gain 6.35, 32.63, 8.2, and 20.04 lbs. of feed for the respective lots.

# DAIRY FARMING-DAIRYING.

Factors influencing the development of dairy heifers, C. H. ECKLES and T. C. Reed (Missouri Sta. Bul. 141 (1916), pp. 26, 27).—Continuing work previously noted (E. S. R., 33, p. 274) efforts are being made to find the protein requirements of growing animals and the normal rate of growth.

One heifer has now been carried from the age of six months to the time of calving at the age twenty-eight months on a ration containing less than 0.5 lb. of digestible protein daily, or about half of that prescribed by the Armsby feeding standard. This amount is apparently below the minimum required, since, although plenty of energy for growth was supplied, the growth of the animal was retarded in both skeleton and tissue development, and her calf was born with rudimentary eyes.

As a control ration with which to regulate the amount of protein and energy as desired and at the same time supply a complete protein, skim milk powder as a source of protein, a small amount of timothy hay for roughage, and a mixture of starch and sugar to supply the energy have been found satisfactory. Mineral matter is added in the form of bone meal and citrates of potassium and magnesium. A heifer on a ration made up in this manner has shown practically normal growth for seven months with a protein consumption of approximately 0.75 lb. per day.

In a preliminary study of the normal rate of growth of dairy heifers it appears that under normal conditions the curve of the growth is very similar for each individual animal. If one animal is below the average in the beginning it is generally about the same distance below the normal during the growing period. Pregnancy exerts but little effect upon the curve of growth, but lactation results in a decided check to growth. A low mineral content of the ration does not show any appreciable effect upon the rate of growth. A ration containing less than half the protein called for by Armsby's standard for growing animals resulted in the animal making 73 per cent of normal growth in height and 54 per cent of normal growth in weight.

Feeding cotton-seed meal and hulls to dairy cows, J. S. Moore (Mississippi Sta. Bul. 174 (1914), pp. 1-10).—In an experiment which lasted over six years, 9 cows in their first lactation period were divided into three lots of 3 cows each; later on 2 heifers were added to each lot. Lot 1 received a heavy ration of cotton-seed meal with little other grain feed and no cotton-seed hulls for roughage; lot 2 received a heavy ration of cotton-seed hulls with no cotton-seed meal; and lot 3 received no cotton-seed products. During the greater part of the first period (180 weeks) the cows were fed the maximum amounts of cotton-seed meal and cotton-seed hulls, and during the second period (144 weeks) they were fed these amounts only when giving a fair yield of milk and when pasture was not available. As a rule, during the second period little cotton-seed meal was fed for 30 days before calving and no cotton-seed meal for a time after calving.

The cows in lot 1 were bred 56 times and dropped 22 calves, with an average of 14 months between calvings; the cows in lot 2 were bred 41 times and dropped 24 calves, with an average of 13 months between calvings; and the cows in lot 3 were bred 29 times and dropped 24 calves, with an average of 12 months between calvings. The average daily production per cow during the first period was for lot 1, 13.7 lbs. of milk and 0.6 lb. of fat; lot 2, 14.3 lbs. of milk and 0.6 lb. of fat; and lot 3, 11.7 lbs. of milk and 0.5 lb. of fat; and during the second period, lot 1, 10 lbs. of milk and 0.45 lb. of fat; lot 2, 12.5 lbs. of milk and 0.54 lb. of fat; and lot 3, 11.9 lbs. of milk and 0.56 lb. fat. Abnormal conditions, if any, occurring in the case of each animal are noted.

"Results indicate that the feeding of 5 lbs. of cotton-seed meal for any length of time is injurious to the dairy cow, causing inflammation of the udder, difficult breeding, and probably having a tendency to cause retention of afterbirth. Feeding cotton-seed hulls in the quantities given appears to cause difficult breeding, though not to the same extent as the feeding of cotton-seed meal. In the above test it has been clearly shown that bad effects may follow the use of cotton-seed meal in too large amounts."

Cotton-seed meal versus cold pressed cotton-seed cake for dairy cows, J. S. Moore (Mississippi Sta. Bul. 174 (1914), pp. 11-13).—In this experiment, which lasted 16 weeks, there were three lots of 7 cows each. During the preliminary period of three weeks all the cows were fed an average ration of 4 lbs. of cotton-seed meal, 7 lbs. of Johnson grass hay, and 42 lbs. of corn silage per head daily. During the next nine weeks each cow received Johnson grass hay and 3 lbs. of wheat bran daily, and in addition lot 1 received 5 lbs. of cotton-seed meal and 2.5 lbs. of cotton-seed hulls, lot 2, 7.5 lbs. of cold pressed cotton-seed cake, and lot 3, 5 lbs. of cotton-seed meal per head daily. During the final four weeks all the cows were fed 4 lbs. of cold pressed cotton-seed cake per head daily on good pasture. The average weekly milk production per cow was as follows: First period, lot 1, 163 lbs., lot 2, 165 lbs., and lot 3, 160 lbs.; second period, lot 1, 144 lbs., lot 2, 151 lbs., and lot 3, 144 lbs.; and third period, lot 1, 155 lbs., lot 2, 158 lbs., and lot 3, 157 lbs.

The cows in lot 1 made an average gain in weight during the 16 weeks of 12 lbs. per head, those in lot 2, 10 lbs. per head, while those in lot 3 lost 4 lbs. each.

The relative value of grain feeds as indicated by former tests at the station is given.

Feeding value of purchased feeds versus pasture versus soiling crops, J. S. Moore (Mississippi Sta. Bul. 174 (1914), pp. 14-16).—This experiment involved three lots of 5 cows each and lasted three periods of six weeks each. During the first period lot 1 received purchased feeds consisting of cotton-seed meal, wheat bran, alfalfa hay, and cotton-seed hulls; the cows in lot 2 were on good pasture of oats and hairy vetch; and the cows in lot 3 were fed alfalfa as a soiling crop. During the second period lot 1 received cotton-seed meal, wheat bran, and alfalfa hay; lot 2 were put on pasture of Bermuda, white clover, smooth vetch, and mixed grasses; and lot 3 were fed alfalfa and Johnson grass as soiling crops. During the third period lot 1 were fed on alfalfa and Johnson grass as soiling crops; lot 2 remained on pasture as in the second period; and lot 3 received purchased feeds. In addition, the cows on pasture and those getting soiling crops received about a half ration of cotton-seed meal, wheat bran, and cotton-seed hulls. All the cows were fed so that each lot would procure about the same amount of milk.

Lot 1, on purchased feeds, gave 10,676 lbs. of milk, the feed cost being \$124.08 and the profit, over cost of feed, \$124.12. The corresponding figures for lot 2, the cows on pasture, were 11,048 lbs., \$50.41, and \$206.39, and for lot 3, those on soiling crops, 10,912 lbs., \$56.79, and \$196.81. In figuring these feed costs and profits cotton-seed meal and wheat bran were valued at \$28 per ton, green alfalfa and green Johnson grass at \$1.50 per ton, Johnson grass hay at \$12 per ton, alfalfa hay at \$15 per ton, cotton-seed hulls at \$8 per ton, and pasture per cow per month 75 cts. Milk was valued at 20 cts. a gallon.

[Dairy husbandry], J. M. Scott (Florida Sta. Rpt. 1915, pp. XIX-XXI).—Individual records of the cows of the station herd show that the feed cost of milk per gallon varied from 7.4 cts. to 20.2 cts. for different cows, the average for the entire herd of 24 cows being 13.6 cts. With milk at 32 cts. per gallon and butter at 40 cts. per pound a much larger profit was obtained from selling milk than from converting it into butter.

The results of an experiment with nine cows to determine the effect that dipping has on milk flow are shown in the following table:

Effect of dipping on milk flow of nine cows.

Period.	First dipping.	Second dipping.	Third dipping.	Fourth dipping.	Fifth dipping.	Sixth dipping.	Total.
Yield 5 days before dipping Yield 5 days after dipping Decrease from dipping	Lbs. 376.9 341.1 35.8	Lbs. 281.5 251.2 30.3	Lbs. 296 264 32	Lbs. 248. 5 211. 9 36. 6	Lbs. 187.7 204.3 a+16.6	Lbs. 187.1 168.1 19.0	Lbs. 1,577.7 1,440.6 137.1

a Indicates increase.

Does it pay to take extra care of cows? C. C. Hayden (Mo. Bul. Ohio Sta., 1 (1916), No. 8, pp. 245-248, figs. 2).—Two cows of the station herd were put under official test conditions for one year. As compared with their previous treatment they were given better care and extra feed, and for a part of the year they were milked three times daily. Under these conditions the first cow, during her fifth lactation period, produced 14,722 lbs. of milk and 400 lbs. of fat, whereas her average production during the first four lactation periods was 8,194 lbs. of milk and 239 lbs. of fat. The production of the other cow during the test, which was her sixth lactation period, was 15,318 lbs. of milk and 505 lbs. of fat, whereas her average producton during the first five lactation periods was 8,195 lbs. of milk and 280 lbs. of fat. In these records one year from the birth of each half was taken as the lactation period.

For the first cow the feed cost during the test was 78 cts. per 100 lbs. of milk and 20 cts. per pound of fat. During her four previous lactation periods the average cost of feed on the same price basis was 89 cts. per 100 lbs. of milk and 22 cts. per pound of fat. For the second cow the corresponding feed costs during the test were 85 cts. and 18.5 cts., and for the first five lactation periods 86 cts. and 18 cts., respectively. For the first cow during the year of the test the total cost was \$1.23 per 100 lbs. of milk and 36 cts. per pound of fat, and for the four previous years on the same basis \$1.57 per 100 lbs. of milk and 45.7 cts. per pound of fat. For the second cow the total cost during the test was \$1.28 per 100 lbs. of milk and 31.6 cts. per pound of fat, and for the five previous lactation periods \$1.54 per 100 lbs. of milk and 38 cts. per pound of fat.

Digest and copy of law regulating the weighing, testing, and purchasing of milk and cream, W. J. Carson (New Jersey Stas. Circ. 62 (1916), pp. 3-16).—In addition to a digest and copy of the law regulating the weighing, testing, and purchasing of milk and cream, the author gives the rules and regulations of the station for its enforcement and a list of creameries in New Jersey.

Cream testing balances, O. F. Hunziker, G. Spitzer, and G. L. Ogle (Indiana Sta. Bul. 189 (1916), pp. 19, figs. 17).—This bulletin presents data concerning the desirability, efficiency, and accuracy of the various types of balances commercially used in the testing of cream for milk fat, outlines notes on their condition, care, and manipulation, and gives specifications and tolerances established by the United States Bureau of Standards for standard cream test balances.

The results of the inspection by the station of 193 balances showed that the sensibility reciprocal, which, as defined by the Bureau of Standards, is the weight required to move the position of equilibrium of the pointer or other indicating device of the balance an amount equal to one division on the graduated scale or arc, averaged 0.0607 gm. with the balances loaded to full capacity and 0.0527 gm. when the balances were without load. The difference in the sensi-

bility reciprocal between balances with and without load was found to be considerably greater in the 6 to 12 bottle balances than in the 1 to 4 bottle balances. It was also found that the 12 bottle balances with and without load are very much less sensitive than the 1 to 4 bottle balances. Of the 193 balances inspected 31 were condemned because they failed to meet the requirement of sensibility reciprocal of 0.1 gm. Some of the balances were condemned because of inaccuracy of graduations on the beam which carries the traveling poise.

A comparison was made of duplicate tests made from the same samples of cream and weighed on a given balance. These tests and retests represented 4,623 samples of cream tested in commercial creameries, and four different types of balances were used. With the use of a one-bottle balance with a sensibility reciprocal of 0.01 gm. and involving 3,540 samples of cream, 96.43 per cent of the retests checked, with a four-bottle balance having a sensibility reciprocal of 0.01 gm. 79.52 per cent of the tests and retests of 376 samples checked; with a twelve-bottle balance having a sensibility reciprocal of 0.01 gm. 80.43 per cent of the tests and retests of 460 samples checked; and with a twelve-bottle balance having a sensibility reciprocal of 0.1 gm. the tests and retests of 247 samples checked in only 60.71 per cent of the cases.

In order to eliminate the effect of differences in technique in preparing the samples of cream and the personal equation in the manipulation of balances, 18 samples of cream were tested in duplicate using 16 different balances with each sample for weighing the cream. The work was done by one person under uniform conditions. With six balances having a sensibility reciprocal of 0.01 gm., and two balances having a sensibility reciprocal of 0.03 gm., 100 per cent of the duplicate tests checked; with two balances having sensibility reciprocals of 0.02 gm. and 0.03 gm., respectively, 94.4 per cent; with three balances having a sensibility reciprocal of 0.05 gm., 92.6 per cent; with one balance having a sensibility reciprocal of 0.08 gm., 77.8 per cent; and with two balances having a sensibility reciprocal of 0.1 gm., only 36.1 per cent. In these tests all duplicate tests varying within 0.5 per cent were counted as checks.

The effect of the degree of sensitiveness in cream balances on the speed of the operator is discussed.

Cooling cream on the farm, O. F. Hunziker, H. C. Mills, and H. B. Switzer (Indiana Sta. Bul. 188 (1916), pp. 1087-1118, figs. 16).—This bulletin reports the results of an experiment to show the effects of cooling cream promptly and properly on the farm.

Each of two cream routes of 20 patrons each of the Purdue University creamery was divided into two parts, and a preliminary test carried on which showed that the two groups were producing cream of similar quality under similar sanitary conditions. One-half of the patrons then received cream-cooling tanks and the other half took care of their cream without the use of special cooling tanks. The cream from each set of patrons was hauled to the creamery twice a week and received the same treatment in the butter-making process. The finished butter was scored at the station by three judges, shipped to New York and there scored by three judges, and sold on the basis of its market value.

During the experiment proper, which extended throughout August, 1915, the weather was wet and unusually cool and consequently the difference between the atmospheric temperature and the temperature of the water used for cooling was comparatively very slight. Notwithstanding this fact, it was found that the use of the cooling tanks produced a very marked improvement in the quality of the cream and of the butter made therefrom. Cream from the patrons using cooling tanks averaged 0.38 per cent acidity and scored 91.25 per cent, and cream from the patrons using no tanks averaged 0.52 per cent acidity and scored 88.75 per cent. It was noted that in the case of the tank cream the

flavor was uniformly clean, while the uncooled cream in most cases had an unpalatable flavor. Bacteriological analyses of the cream showed that the average reduction of micro-organisms ascribed to the use of cooling tanks in this experiment was 35 per cent of the total bacterial content, 35.8 per cent of the lactic acid bacteria, 72 per cent of the liquefiers, and 75 per cent of the undesirable yeast and molds. In fermentation tests the cooled cream produced a solid curd with a sharp separation of a clean whey. The majority of the fermentation tests from the uncooled cream showed a gassy curd and in some cases the curd underwent decomposition.

Analyses of all the experimental butter for moisture, salt, and curd showed average percentages about the same for each set of butter. Bacteriological analyses of samples of butter from each of the experimental churnings showed the following reductions ascribed to the use of the cooling tank. Total bacteria 58.6 per cent, acidifiers 60.2 per cent, liquefiers 81.9 per cent, and yeast and molds 87.4 per cent. The average score of the butter made from the uncooled cream was 88.98 at the station, and two weeks later at New York 87.69, and for the butter made from the cooled cream 91.63 at the station, and 89.7 at New York. With one exception the cooled-cream butter scored uniformly higher than the uncooled-cream butter, both at the station and at New York. On the open market in New York the price received for the cooled-cream butter was 24.88 cts. per pound, and for the uncooled-cream butter 23.94 cts. per pound.

The bulletin points out the essential features of satisfactory cream cooling tanks, gives notes on the use of springs and wells for cooling cream, and describes several types of homemade and commercial cooling tanks.

Progressive exidation of cold-storage butter, D. C. Dyer (U. S. Dept. Agr., Jour. Agr. Research, 6 (1916), No. 24, pp. 927-952, pl. 1, fig. 1).—In preliminary work in this investigation, which was conducted in the Dairy Division of the Bureau of Animal Industry, the attempt was made to determine whether the undesirable flavors of storage butter arise from a decomposition occurring in the fat itself or in some one or more of the other components entering into the composition of the whole product. Examination of the air inclosed within packages of butter differently prepared and in butter fat alone was made with a specially designed gas apparatus which is illustrated and its manipulation described.

Very little alteration was found to occur in the composition of the air inclosed in sweet cream butter made from cream having an acidity (calculated as lactic acid) of 0.11 per cent when it was kept for about six months at a temperature of 0° F. A perceptible change in composition of the inclosed air was found when the butter was kept at a temperature of 32° and a very noticeable change when it was kept at room temperature. The sample of butter used, which contained a considerable number of bacteria, scored 92 when made, 91 at the end of three months, and 90 at six months when stored at 0°. At no time was there a trace of undesirable flavor.

An analysis was made of air extracted from butter made from sweet cream churned immediately after the addition of 15 per cent of a commercial starter. At the time of churning this cream had an acidity of 0.25 per cent. The butter made from this cream showed, so far as the composition of the air inclosed in it was concerned, a comparatively slight variation from that observed in the previous case of sweet-cream butter, when both samples were stored at a temperature of 0°. This butter scored 92 when made and 89 after 6.5 months, with no variation in flavor. Butter was also made from sweet cream churned immediately after the addition of lactic acid. The acidity of this cream was 0.71 per cent. On analysis the air extracted from a sample of this butter showed a pronounced decrease in the oxygen and carbon-dioxid content, even

when the butter was stored at a temperature of 0°, and this decrease was still more marked when it was allowed to remain at a temperature of 32°. This butter, stored at 0°, scored 93 when made, 88 at three months, and 84 at six months, and had a pronounced unclean flavor at the end of this time.

From these analyses it is concluded that the decomposition caused by cream acidity progresses at a temperature of  $0^{\circ}$  in a package of butter and can be measured by an analysis of the gas extracted therefrom.

A series of experiments was then undertaken to determine whether this measurable decomposition occurs in the fat of the butter itself, in the buttermilk, or in both. Fat from butter made from pasteurized cream was so prepared as to exclude, as far as possible, by melting, filtering, and washing, all ingredients of the butter other than fat. The butter fat so prepared was found to contain 0.05 per cent of protein ( $N\times6.38$ ). Samples of this fat kept in storage at 0° showed no physical alteration of any kind after six months or even after 1.5 years. Analyses showed that no chemical changes had occurred in fat kept in storage under these conditions for months, and an analysis of the extracted air showed that no appreciable oxidation had occurred during a storage interval of five months. A sample of this purified butter fat was exposed to the action of a large quantity of air and stored for about three and a half months at 32°. Under these conditions very little oxidation took place.

To determine whether oxidation takes place in one or more of the nonfatty constituents, butter was made from pasteurized cream ripened with a pure culture. A part of this butter was washed until the wash water was barely clear; another part was given additional copious washing in four changes of water; and with the third part the buttermilk was drawn off and the butter allowed to remain unwashed. Each of these samples was worked on a table worker to the extent of 40 revolutions. During the storage period the excessively washed butter and the normally washed butter were found to have practically the same keeping qualities as shown by scoring, and the chemical constants of the fat showed that there was very little or no chemical change. However, analyses of the confined air in these samples showed that the total amount of oxygen originally present underwent a markedly progressive decrease during storage at 0°. The sample of unwashed butter scored 92 at one month and 86 at six months, at which time it was stale, fishy, and sour. No noteworthy chemical change had occurred in the fat at six months, but striking changes had occurred in the composition of the confined air. The maximum amount of carbon dioxid (31.67 per cent) was found after a storage of three months, at about which time the characteristic "off-flavor" became distinctly noticeable. Very little oxygen was found in the sample after two months' storage. With another sample of unwashed butter 19.89 per cent of carbon dioxid was found in the butter 1.5 hours after manufacturing. This amount increased to 22.91 per cent at the end of two weeks when the butter was held in the dark at room temperature. Under these conditions the oxygen content decreased from 20.42 per cent at 1.5 hours to 10.61 per cent at the end of two weeks.

To further test the effect of air on the nonfatty ingredients of butter, tubes filled with broken pumice were impregnated with buttermilk from butter made from pasteurized cream acidified to 1 per cent with lactic acid before churning. This acid buttermilk was held at 32°. When the buttermilk was 4.5 days old it was found to contain 17.67 per cent of oxygen. At 26 days the oxygen content had decreased to zero. The carbon dioxid content of the buttermilk rose from 2.37 per cent at 4.5 days to 34.37 per cent at 26 days and decreased to 31.76 per cent at 62 days. In a control experiment with a 1 per cent solution of lactic acid the oxygen content remained practically constant and at

no time was there any carbon dioxid present. In a similar experiment with buttermilk from sweet cream butter made from pasteurized cream having an acidity of 0.108 per cent the inclosed air underwent practically no change in 270 days' storage at 0°.

The author summarizes the investigations as follows: "The development of undesirable flavors in butter held in cold storage at a temperature of 0° is not dependent upon an oxidation of the fat itself. The production of 'off-flavors' so commonly met with in cold-storage butter is attributable to a chemical change expressed through a slow oxidation progressing in some one or more of the nonfatty substances occurring in the buttermilk. The extent of this chemical change is directly proportional to the quantity of acid present in the cream from which the butter was prepared. The quantity of carbon dioxid present in cold-storage butter appears to have a certain relation to the quantity of buttermilk in the butter. During storage this quantity of carbon dioxid may increase to a maximum followed by a progressive decrease."

#### VETERINARY MEDICINE.

Live stock disease investigations, L. B. Barber (Guam Sta. Rpt. 1915, pp. 25-41, pls. 2, figs. 4).—Cattle ticks, which are so widely spread on the island that few calves succeed in avoiding serious infestation, are said to constitute the greatest obstacle in the way of the cattle industry in Guam. B. H. Ransom of the U. S. Department of Agriculture has identified the species as Margaropus annulatus caudatus, and the author has been unable to differentiate the ticks infesting cattle and those on horses, carabaos, goats, and deer. That serious infestation takes place during the dry season it is thought may be explained in part by the fact that the cattle at that time of the year are usually in poor condition due to the absence of proper feed.

Observations on the biology of this tick indicate that the life history is essentially the same as that of *M. annulatus*. Temperature charts of animals severely infested with ticks are presented and discussed. Examinations of the blood of an animal during periods of high fever have shown the presence of a parasite that is smaller than *Piroplasma bigeminum*.

Comparatively few fenced pastures are to be found in Guam, and practically all the cattle that are not running in more or less of a wild state in the interior of the island are used as cart animals, traveling from village to village and from ranch to ranch, thus making it exceedingly difficult to maintain and enforce a quarantine. In eradication work, the horses, carabaos, goats, and deer as well would have to be taken into consideration.

Liver flukes (Fasciola hepatica) have been found to infest cattle, hogs, and goats. A post-mortem examination of 32 beef carcasses at the city market in Agana showed 26 livers to be infested and 4 gave evidence of previous infestation with flukes, while 9 livers of 14 hog carcasses inspected were infested and 2 showed the effects of flukes. The livers of some of the cattle examined were almost totally destroyed by the flukes, though the animals appeared to be in a fairly healthy condition. Few, if any, cattle succumb as a direct result of fluke infestation, but the fluke undoubtedly materially checks the growth and influences to a considerable degree the normal development of a young animal. Infestation of goats and swine, especially the former, is apparently more serious, and if allowed to remain uncorrected eventually will result in a high mortality. Among the preventive measures mentioned the author suggests the introduction of frogs and toads, which do not occur on the island, to assist in the eradication of snails, the intermediate hosts.

A stomach worm, thought to be Hamonchus contortus, has been found on the island in only one case, that of a native cow.

It is said that the seriousness of the parasitic infestation of swine can hardly be overestimated. The kidney worm (Stephanurus dentatus) and a lungworm, probably Strongylus paradoxus, are important parasites, the latter causing the most serious and fatal disease of swine on the island.

Coccidial white diarrhea is said to cause large losses among chicks at the station. Success in combating this disease has resulted from proper care, including the use of a medicated drinking water made up of 1 gal. of bichlorid of mercury solution (1:10,000), 3 grains of citric acid, and one 30-gm. sulphocarbolate tablet. In tests made of the efficacy of this treatment, it was found that the chicks not given the medicinal drinking water nearly all succumbed, whereas those receiving it have not averaged a loss of more than two chicks per hatch. It is stated that in the absence of proper treatment and the presence of such predisposing causes as improper brooding and poor feeding the mortality will run between 90 and 100 per cent, whereas by eliminating all predisposing causes and using the treatment above recommended the mortality should be reduced to 5 per cent or less.

Chickenpox or sorehead is the most widely disseminated poultry disease on the island. Chicken cholera is said to have done more to discourage the poultry industry than any other factor, two outbreaks having been investigated during the year. Diphtheritic roup is present in all parts of the island, investigations having shown as many as 50 per cent of a brood of young chicks to be affected, and the mortality among untreated chicks going as high as 90 per cent.

The endoparasites of poultry mentioned as occurring on the island are several species of tapeworm, the common roundworm, the ceca worm, small round worms which inhabit the proventriculus, and at least one species of eye worm. Eighteen per cent of chicks between four and six months of age which died at the station were found to be infested with a nematode, probably Tetrameres fissispinus. The eye worm, which resembles Manson's eye worm, is said to be commonly found infesting the native fowls. Ectoparasites mentioned are two species of lice, Menopon pallidum and Goniocotes gigas and a mite, Dermanyssus gallinæ.

[Report of the veterinary department], J. W. Connaway and A. J. Durant (Missouri Sta. Bul. 141 (1916), pp. 39-42).—In hog-cholera immunity investigations, continuing the studies previously noted (E. S. R., 33, p. 278), "negative results were obtained with the experimental antigen prepared from the blood, kidneys, and lymph nodes of a few pigs suffering from the acute hemorrhagic type of cholera. More extensive work was done with spleen antigens from acute cholera cases, and ulcer antigens from chronic cases, and better results were obtained."

The results obtained clearly demonstrated that a distinct complementfixation reaction occurred with the serum of cholera-immune hogs when an extract from the spleen pulp of an animal that had died from an attack of the acute hemorrhagic type of the disease was used as antigen.

"The question remains open, however, as to whether the results obtained were due to a specific hog-cholera antigen in the spleen extracts, or to associated antigens. But in this connection it is pertinent to state that the cholera spleen from which the experimental antigens were prepared failed to yield cultures of the Salmon bacillus (Bacillus suipestifer), the micro-organism most commonly associated with the filterable virus of hog cholera. Moreover, tests made with an antigen prepared from a pure culture of B. suipestifer gave no deviation of

the complement with serum samples obtained from hogs which gave a positive reaction to the spleen antigen extracts."

Experimental antigens were also prepared from the intestinal button ulcers of hogs affected with the chronic type of the disease. No definite conclusions, however, could be drawn from the positive reactions obtained with these antigens, since the necrotic ulcers used undoubtedly contained "a number of contaminating micro-organisms and toxic products which have no causative relation to hog cholera but which under certain conditions possibly may stimulate the production of their special antibodies in the blood of a cholera-infected hog. B. coli communis, B. suipestifer, B. necrophorus, and Spirochæla hyos have all been found in these ulcers,"

Small quantities of the positive-reacting ulcer material injected into susceptible pigs produced typical cases of hog cholera. Preliminary data indicate the possibility of ultimately using the complement-fixation test in determining the variations in the potency of serum. An attempt is being made to isolate the antigen from the positive-reacting spleens and ulcers in as pure a form as possible.

In contagious abortion investigations, "29 suspected herds, comprising a total of 610 cattle, have been tested. Including animals retested, 1,218 blood-serum samples have been examined. Twenty-four, or a little over 80 per cent, of the suspected herds contained positive-reacting animals with a history of abortion. In one herd, in a group of 70 cows, 41 gave a positive reaction, and 29 a negative reaction. . . . In other herds the percentage of positive reactors was less. Taking the entire number of animals tested in the infected herds 43 per cent gave a positive reaction."

The value of the test to the cattle owner in preventing the spread of the infection and in its eradication is indicated.

Text-book of meat hygiene, R. Edelmann (Lehrbuch der Fleischhygiene. Jena: Gustav Fischer, 1914, 3. rev. ed., pp. XVI+442, pls. 4 figs. 221).—The third revised German edition of this work, of which American editions have been previously noted (E. S. R., 35, p. 681).

The physical chemistry of disinfection, I, J. F. Norton and P. H. Hsu (Jour. Infect. Diseases, 18 (1916), No. 2, pp. 180-194, fig. 1).—The results of the study reported are summarized as follows:

Acids act as disinfectants through the agency of the hydrogen ions produced by electrolytic dissociation. The disinfecting power of an acid is approximately proportional to the hydrogen-ion concentration. The addition to an acid of a salt containing an anion common to this acid diminishes its disinfecting power, as the result of a decrease in the hydrogen-ion concentration and an increase in the concentration of the undissociated acid molecules. Salts which do not appreciably affect the dissociation of an acid greatly increase the disinfecting properties of the acid. Acid anions are positive catalyzers and undissociated acid molecules are negative catalyzers in acid disinfection.

The early determination of pregnancy in domestic animals, E. R. Wecke (Flugschr. Deut. Gesell. Züchtungsk., No. 35 (1915), pp. 56).—This pamphlet discusses the importance to the breeder of an early diagnosis of pregnancy, the methods commonly employed, the theoretical principles of the dialysis procedure, and the anatomical possibilities of the entrance of fetal material into the circulating blood of the mother. The dialysis method and its manipulation are described in detail.

From experimental data reported the author concludes that the dialysis procedure is a valuable and accurate method for the determination of pregnancy in cattle, especially in the early stages where the usual means of

diagnosis are unreliable. A bibliography of 47 references to the literature is included.

The variations in reaction of the blood of different species as indicated by hemolysis of the red blood cells when treated with acids or alkalis, J. G. Cumming (Jour. Infect. Diseases, 18 (1916), No. 2, pp. 151-179, figs. 11).—The author reports hemolytic and chemical time indexes and their equivalent NH₃, NaOH, and HCl percentages of the erythrocytes of the dog, bear, horse, mule, white rat, brown rat, turtle, guinea pig, rabbit, frog, pigeon, hog, monkey, chicken, cat, elephant, cow, deer, sheep, goat, negro, and Caucasian.

"For the 15-minute hemolytic system there is a marked difference in the chemical requirements (NH₃, NaOH, and HCl) for some species, while the difference is not so marked for others. For this system one of the three chemical hemolysins may be of the same percentage for two species; invariably there appears, however, a difference in the percentage requirement for either one or both of the other two chemical hemolysins. The NH₃ hemolytic time indexes divide the animals tested into four fairly distinct groupings. The position of the NaOH hemolytic time indexes of the different species corresponds closely to that of the NH₃ indexes. There is no special arrangement of the HCl time indexes for the different species with relation to the alkaline indexes." Alkaline hemolysis is deemed due to the OH group and acid hemolysis to the H ion.

It is indicated that the chemical and hemolytic time indexes may be used to identify blood-cell suspensions of different species with a considerable degree of accuracy. The hemolysis of the red blood cell may be used as an indicator to determine the degree of acidity or alkalinity of certain solutions. As an indicator these cells are affected by the isotonicity of the blood suspension. "Alkaline hemolysis can be influenced by acids, and acid hemolysis by alkalis. Both acid and alkaline hemolysis can be influenced by the neutral salt content of the suspension."

A distinct variation between the normal and pathological blood of the same species was observed in most of the specimens tested. This variation is deemed probably due to an increased alkalinity or decreased acidity or to variation in the neutral salt content.

A practical method for the identification of guinea pigs under treatment, A. P. HITCHENS (Jour. Bact., 1 (1916), No. 5, pp. 541-545, fbg. 1).—A system for identifying laboratory animals based on a study of abbreviations is described. It is indicated that by this system animals can be both rapidly described and easily recognized.

The anticoagulant action of acid anilin dyes toward albuminous materials, A. C. Hollande (Compt. Rend. Acad. Sci. [Paris], 162 (1916), No. 25, pp. 959-961).—From experiments made by treating ascitic fluid, cerebro-spinal fluid, pleural exudate, ovalbumin, etc., with various acid and basic dyes, as eosin, orange G, uranin, Congo red, light green, etc. (equal volumes of fluid and 2 per cent solutions of the dye), it was found that the acid dyes combined with the protein substances and formed colored acid albumins. These substances were not coagulated at the boiling temperature or on being sterilized in an autoclave at 120° C. for 20 minutes.

On boiling a mixture of a soluble protein and an acid dye a transparent jelly was obtained which could be further heated at 120° without changing its character. It is indicated that by the proper choice of a nontoxic acid dye media suitable for bacteriological use can be prepared in this manner.

It is further indicated that the property possessed by the acid dyes of combining with protein material substantiates the idea that histological staining is a physicochemical reaction (eosinophilic, acidophilic), and not merely a purely physical (adsorption, solution) action.

A method of studying the effect of serum upon tissues, S. Feldstein (*Proc. Soc. Expt. Biol. and Med., 12 (1915), No. 8, pp. 187–191*).—A histological method for studying the effect of serum on various tissues is described in detail.

After incubation of the tissue with serum and proper staining marked changes in the structure were observed, the most striking changes being found in the nuclei. The nuclei had either disappeared entirely or failed to take the stain.

The results are briefly discussed.

The effect of lecithin and horse serum on the hemolytic action of certain peptones, A. A. Epstein (Jour. Immunol., 1 (1916), No. 3, pp. 183-188).—Continuing previous work at the author has shown that lecithin alters the hemolytic and agglutinative action of the peptones in relation to different species of red blood cells.

"It seems apparent that the increase in the hemolytic activity of the peptones resulting from the addition of minute amounts of lecithin is not due to the intervention of a lipolytic ferment and the subsequent splitting off of a fatty acid from the lecithin."

The activation of the peptones can be accomplished not only by the addition of pure lecithin to them but also by the addition of horse serum, as in the case of cobra venom. The activation of the peptones with serum is not so marked as with the lecithin. Whole serum fails to activate the peptones and interferes with their hemolytic action. After extraction with ether the serum does not activate the peptones in any dilution.

The relation of lipoids to immune reactions, J. W. Jobling (Jour. Immunol., 1 (1916), No. 4, pp. 491-500).—This is the presidential address delivered at the third annual meeting of the American Association of Immunologists, held at Washington, D. C., May 11 and 12, 1916. The subject is reviewed in detail and a bibliography of 67 references to the literature cited is appended.

A new method of active immunization, M. Frankenhuis (*Tijdschr. Diergeneesk.*, 48 (1916), No. 16, pp. 597-602).—A method of immunization which depends on the slow, continued absorption of the virus is described. The virus is introduced into the animal in a capillary tube which is placed under the skin by a rather simple operation. The slow absorption takes place from the material introduced. A permanent active immunity is thus obtained, as indicated by experimental data submitted.

The use of the new procedure as a prophylactic against spotted fever and foot-and-mouth disease is suggested and outlined. Advantages claimed for it are that it is not dangerous even though the lethal dose is introduced; a greater and more permanent immunity can be obtained than with any of the other methods in general use; immunization is possible even though no pure culture is at hand; and the method can be used in conjunction with other methods if desired.

The introduction of the capillary tube as foreign material is indicated as a disadvantage, although the danger with sterile material is deemed to be slight.

A simplified method of producing a potent precipitin serum, W. V. SMITH (Jour. Med. Research, 34 (1916), No. 2, pp. 169-175).—In cases where human blood or blood serum can not be readily obtained at all times the author recommends the precipitation of the protein with ammonium sulphate and the use of the precipitate for the production of a potent precipitin rabbit serum by intraperitoneal injection. The preparation thus obtained can be kept on hand for a long time, "at least nine months, and no doubt indefinitely." The danger to the animal to be injected is greatly reduced by using the concentrated material, as a smaller quantity is injected and the preparation is sterile, or nearly so.

Serum osmose. The treatment of wounds by blood serum obtained through osmosis, P. Chatelain (Rec. Méd. Vét., 92 (1916), No. 13, pp. 393-397).—The author describes a procedure for wound treatment in which either powdered sodium chlorid or a solution of suitable strength of the salt is used as a dressing. By this treatment the wound becomes naturally saturated with the blood serum.

The results of the new treatment indicate that the use of sodium chlorid is superior to the use of either boric or picric acid. Suppuration is checked immediately and cicatrization is rapid and complete.

The specific serum treatment of wounds, E. Leclainche and H. Vallée (*Rev. Gén. Méd. Vét.*, 25 (1916), No. 295, pp. 306-316).—This is a general discussion of the treatment of wounds with polyvalent sera either by injection or direct local application as recently introduced by the authors.

The destruction of anthrax spores in hides and skins by caustic soda, E. Haller (Arb. K. Gsndhtsamt., 50 (1915), No. 1, pp. 96-121).—A 0.5 to 1 per cent solution of caustic soda at a temperature of 15 to 20° C. (59 to 68° F.) was found to destroy anthrax spores in cattle hides and sheep and goat skins. The germicidal action of the solution was increased by the addition of a 5 to 10 per cent solution of sodium chlorid, the spores being destroyed in 72 hours in almost all the cattle hides and sheep skins tested.

Experimental studies on the immunity of foot-and-mouth disease, C. TERNI (Clin. Vet. [Milan], Rass. Pol. Sanit. e Ig., 39 (1916), No. 9, pp. 257-261).—The author has found that the virus of foot-and-mouth disease can be preserved indefinitely by the passage of virulent blood, as well as the product of the local lesions, through sensitized animals. The best procedure for conserving the virulence and controlling an active infection of the virus was found to be the use of infective material from the blood of an animal in a high febrile condition or the product of the local lesions. Other species of animals harbor the virus of the disease through various periods of time without manifesting any external symptoms. With the blood preserved in a thermostat after being attenuated by cooling a resistance to the disease can be obtained by the successive inoculation of the virus which is much greater than that manifested by animals which have survived a severe case of the disease. The blood serum of animals which have survived the disease possesses remarkable prophylactic properties against the virus, and the inoculation of such blood containing the maximum amount of antibodies causes a rapid recovery of animals in advanced stages of the disease. Practical serotherapy thus seems to be possible.

Two forms of immunity are distinguished, a general immunity localized in the blood, especially in the white corpuscles (eosinophils?), red corpuscles, and plasma, and another localized in the protective epithelium. The latter is indicated as being the most permanent.

The clinical form of the disease varies in degree according to the previously existing immunity. On post-mortem examination of animals which had died from the disease the virus was found to be localized in different organs, especially in the cardiac muscles, brain, liver, and kidneys. Less was found in the spleen and in the bone marrow.

In the epithelial lesions two substances were found (granulo-stimoline and granulo-lysin) which are indicated as possessing chemotactic properties which produce an eosinophilia.

Tuberculosis of the seminal vesicles, vas deferens, and urethra in the bovine, P. Chaussé (Rec. Méd. Vét., 92 (1916), No. 13, pp. 397-408, figs. 3).—The author reports a case and describes the lesions and histopathological findings. The probable route of infection in the case reported and similar ones is discussed.

The influence of tuberculosis on the chemical composition of the animal body, K. Dröge (Pflüger's Arch. Physiol., 163 (1916), No. 4-6, pp. 266-288, pls. 2).—Analytical data of the chemical composition of normal and tubercular guinea pigs are reported in detail. The weights of the animals, taken weekly over a period of a number of months, and the post-mortem findings in a number of animals are also reported.

While the data show a normal fat content in animals in which there was either no active infection or a process of recovery and a low fat content in severely infected animals or animals which had died from the disease, the author contends that a high fat content with an increased resistance or a low fat content with a decreased resistance is not necessarily always the case. In slightly affected animals the water content was found to be normal, while in acutely affected animals a considerable increase was noted.

The data submitted, together with that reported by earlier investigators, are discussed in detail.

Studies in immunity to tuberculosis, A. K. Krause (Jour. Med. Research. 35 (1916), No. 1, pp. 1-50).—Three studies are reported.

I. Experimental studies on the cutaneous reaction to tuberculo-protein.—Factors governing the reaction (pp. 1-23).—It was found that cutaneous hypersensitiveness to tuberculo-protein is inaugurated by the establishment of infection and the development of the initial focus. The hypersensitiveness increases with progressive disease and varies directly with the extent and intensity of the disease. With the healing of the disease it diminishes but is probably never entirely lost (except in the presence of intercurrent disease, pregnancy, etc.). It is increased by reinfection and diminished or completely wiped out during the period of general tuberculin reaction.

It is suggested that "tissue hypersensitiveness may be a function of immunity to reinfection."

II. The anaphylactic state in its relation to resistance to tuberculous infection and tuberculous disease.—An experimental study (pp. 25-42).—"Anaphylactic shock, experienced by guinea pigs a short time before infection with tubercle bacilli of low virulence, did not reduce their resistance to such an extent that the parasitism of the particular micro-organism concerned was markedly increased, although there were suggestions that the extent of disease was probably increased. If tuberculous disease of low grade is once established in guinea pigs a single attack of anaphylaxis does not bring about conditions that favor the extension of the disease. Anaphylactic shock suffered just before the inoculation of a nonpathogenic acid-fast organism, the Mist bacillus [Möller's grass bacillus], does not lay the body open to progressive invasion by this germ.

"No success attended the efforts to enhance the virulence of a strain of the tubercle bacillus (*R1*) when the method of Thiele and Embleton was followed. Evidence is submitted that tubercle bacilli can preserve their viability and their original virulence after being kept in a dried state for as long a time as from 15 to 17 months."

III. Concerning the general tuberculin reaction (pp. 43-50).—"An extract of an animal's own normal tissues if introduced rapidly into its circulation is toxic. The products of tuberculous foci are primarily toxic if received into the blood stream (or, perhaps, lymph stream)."

It is suggested that "the symptoms of the general tuberculin reaction are due to the primary toxicity of focal products, the absorption of which is favored by the focal reaction that results from the injection of tuberculin."

The antigenic properties of tubercle wax, B. Lucke (Jour. Immunol., 1 (1916), No. 4, pp. 457-464).—From a study on the possible antigenic value in serum diagnosis of tubercle wax the author found that the wax antigens caused

complement deviation with a high percentage of sera possessing lipotropic properties. "These antigens also cause complement deviation with a moderate percentage of presumably normal and tuberculous sera."

It is indicated that such antigens possess neither diagnostic nor prognostic value in the serum diagnosis of tuberculosis.

Present status of the infectious abortion problem, L. R. HIMMELBERGER (Amer. Jour. Vet. Med., 11 (1916), No. 9, pp. 699-702).—This article briefly reviews the more recent literature concerning the progress being made with a general view to combat the disease.

Some experiments with bacterial vaccines for the cure of splenetic tick fever in cattle, R. L. Rhea and G. W. Mackie (*Jour. Amer. Vet. Med. Assoc.*, 49 (1916), No. 3, pp. 361-365).—The etiology, symptoms, post-mortem lesions. and differential diagnosis of the disease are briefly reviewed.

The experimental work reported covered a period of six months. One hundred and forty cases were treated, 118 of which made good recovery. The cattle ranged in age from eight months to aged animals. The vaccine used was a combined streptococcus and staphylococcus.

It is indicated that "the body of all animals is at all times the host of microorganisms which are incapable of setting up disturbances when the body has a high resistance, but if for any reason the body resistance should drop below normal in vitality these same latent organisms may become pathogenic. The infection producing tick fever primarily is *Piroplasma bigeminum*; however, when by its action the resistance of the body is reduced below normal, these organisms may cause a secondary infection and with their toxins may assist in producing symptoms which accompany tick fever. . . . The fact that immunity can be established by blood inoculations warrants us in saying that antibodies may be produced in the blood by proper stimulus, and as the agent used in this test work is a streptococcus and staphylococcus vaccine [and] antibodies produced by this type of vaccine combat only that type of invasion we may conclude they play an important rôle in this disease."

The action of organic body fluids on the bacillus of swine erysipelas, V. Colomo (Bol. Inst. Nac. Hig. Alfonso XIII, 12 (1916), No. 46, pp. 87-97).—Serological experiments are reported from which the author concludes that the antiserum of swine erysipelas obtained from rabbits possesses agglutinative and bacteriotropic properties the same as that obtained from the horse. The bone marrow contains rather large amounts of antibodies, although not so great as might have been expected. The blood of immune rabbits is richest in agglutinins.

In conformity with earlier views the spleen was found to have no defensive rôle against septicemical infections. The same may be affirmed of the other organs with the exception of the bone marrow. Antibodies were found in sufficient quantities in the bone marrow to have a detrimental action on the bacillus of the disease, a fact which is in agreement with earlier investigations in which considerable quantities of antibodies of typhoid fever and pneumonia were found in the bone marrow.

Report to the council of the National Pig Breeders' Association on the present state of knowledge of swine fever with special reference to the available statistics, M. Greenwood, Jr. (Borrowash, England: Nat. Pig Breeders' Assoc., 1914, pp. 69+III).—This material has been previously noted from another source (E. S. R., 32, p. 881).

The results of the use of hog-cholera globulin on three thousand hogs in the field, R. Graham (Amer. Jour. Vet. Med., 11 (1916), No. 9, pp. 703-707).—Detailed experimental results are reported, from which the author concludes that hog-cholera globulin possesses immunizing properties equal to the whole

unrefined cholera serum. The globulin was found to protect against natural exposure and artificial infection (1 to 5 cc. virus) in doses of 0.2 cc. per pound weight. On account of its concentration the globulin may be used in much smaller doses and thus offers the advantage of reducing the labor of administration. "It seems reasonable to assume that a small immunizing dose is absorbed more rapidly by the animal as the units of value are more quickly available." Being a sterile product, it is found more desirable for use than the unrefined serum.

Hog cholera in Pennsylvania, R. M. Staley (Penn. Live Stock Sanit. Bd. Circ. 43 (1916), pp. 13).—This bulletin discusses the distribution, symptoms and lesions, cause, methods of spreading the disease, treatment, prevention, and the serum-virus and serum-alone treatments. Regulations with reference to hog cholera adopted by the State Live Stock Sanitary Board to protect and encourage the swine industry of Pennsylvania are included.

The maintenance of virulence of Bacillus abortivus equinus, E. S. Good and W. V. Smith (Jour. Med. Research, 33 (1916), No. 3, pp. 493-498).—In a study of the virulence of certain cultures of B. abortivus equinus, it was found that the intravenous inoculation of a mare with 1 cc. of a mixed culture of the organism which had been grown in the laboratory at the Kentucky Experiment Station for from 10 to 30 generations and for from one and a half to four years caused a typical abortion. Previous tests of the animal's blood showed no immunity to the disease. At the time of inoculation the animal was protected with 200 cc. of a hyperimmune serum which possessed marked bacteriolytic properties.

The intravenous inoculation of 0.1 cc. of 24-hour broth cultures produced death in rabbits in from two to four days, and the subcutaneous inoculation of 1 cc. of a broth culture produced abortion in guinea pigs in four days and seventeen days. The organism producing these effects was in each instance isolated from the animal after death.

Contagious epithelioma in chickens (chicken pox, swelled head).—Its control by vaccination, W. B. MACK and E. RECORDS (Nevada Sta. Bul. 84 (1916). pp. 3-32, figs. 19).—A popular abstract of Bulletin 82 (E. S. R., 34, p. 189) amplified and illustrated.

#### RURAL ENGINEERING.

Official proceedings of the Twenty-first International Irrigation Congress held at Calgary, Alberta, Canada, October 5-9, 1914 (Off. Proc. Internat. Irrig. Cong., 21 (1914), pp. XXVIII+402, pls. 9, figs. 31).—These proceedings contain the following special articles bearing on the subject of irrigation: Failure of Irrigation and Land Settlement Policies of the Western States, Water Storage and Distribution by the United States Reclamation Service, The Dominion Government Laws Respecting Irrigation in Western Canada, Colonizing in Western Canada, British Columbia Irrigation Policies, The Necessity of a Higher Duty of Water, Farm Development in the Arid West, Administration of Water Rights in British Columbia, Irrigation and Saskatchewan Agriculture, Relation of the Farmer to the Irrigation Project, Irrigation in Alberta and the Settler on Irrigated Land, Some Irrigation Problems in Texas, Recent Irrigation District Legislation in California, Irrigation Enterprises of the Canadian Pacific Railway Company in Alberta, Storage and Power Possibilities of the Bow River West of Calgary, The Great Falls Plan of Cooperation between the City and Farming Community, Silt Problems of the Colorado River, and Irrigation Conditions in the State of Washington.

Report of the undersecretary of state on the Ministry of Public Works, 1914-15 (Rpt. Min. Pub. Works Egypt, 1914-15, pp. VII+126, pls. 21).—This report deals especially with irrigation and irrigation works in Egypt.

The flow of water over sharp-edged notches and weirs, H. J. F. GOURLEY and B. S. CRIMP (*Minutes Proc. Inst. Civ. Engin.* [England], 200 (1915), pt. 2, pp. 388-408, figs. 4).—Experiments on the flow of water over sharp-edged, triangular, and rectangular weir notches are reported.

It was found that "the flow over a triangular notch is proportional to  $H^{2.47}$  and varies in direct proportion to the ratio of width to height. The general law is Q=2.48, n.  $H^{2.47}$ , in which Q is the discharge in cubic feet per second, n the tangent of half the included angle of the notch, and H the head in feet.

"The flow over any trapezoidal notch is equal to the flow over a rectangular weir of equal length with two end contractions plus the flow through a triangular notch of corresponding angle.

"The flow over a rectangular weir with end contractions varies as  $H^{1,47}$  and increases rather more rapidly than the length, i. e., as  $L^{1,02}$ , and is given by the formula  $Q=3.10\ L^{1,02}\ H^{1,47}$ , which applies to all weirs up to at least 19 feet in length, and, to judge from the comparisons made for short weirs, for heads up to half the length of the weir, provided the depth of pool below the sill of the weir is not less than twice the head. In the formula, Q is cubic feet per second, L the length in feet, and H the head in feet."

Abnormal coefficients of the Venturi meter, A. H. Gibson (Minutes Proc. Inst. Civ. Engin. [England], 199 (1915), pt. 1, pp. 391-408, pl. 1).—Investigations conducted at University College, Dundee, on the causes of abnormal values of the coefficient C used in the base formula for the venturi meter,

 $Q = CA\sqrt{\frac{2gh}{m^2-1}}$  are reported which led to the following conclusions:

"In any meter, in good order and of normal proportions, friction does not affect the value of  $\mathcal{C}$  by more than about 2 per cent so long as the diameter of the pipe line is greater than about 2 in. For large meters at velocities exceeding 1 ft. per second the effect is in general less than 1 per cent. The effect increases very slightly with a diminution in velocity. With pipe line velocities less than about 0.5 ft. per second the steadying of the velocity at the throat causes a distribution of velocity under which the kinetic energy at the throat

is appreciably greater than  $\frac{v^2}{2g}$  feet. In a meter fitted with the usual U-tube gage, or any modification of this type, this may reduce the apparent value of C to a minimum of about 0.75 at low velocities. Values of C obtained from a meter when measuring a pulsating flow are less than with constant flow. If k is the proportional fluctuation of velocity per cycle on each side of the mean, C

is reduced in the ratio  $1 \div \sqrt{1 + \frac{k^2}{2}}$ . Except, as where used for metering the discharge from a reciprocating pump, k may be large, any such effect is in general small.

"The effect of whirl in the water approaching the meter is to increase the value of C. The effect is, however, small; is approximately constant at all velocities; and it is extremely improbable that in the normal pipe line it exceeds about 1 per cent.

"Where the pressure orifice at throat or entrance of a meter consists of a circumferential gap, the width of this gap has some effect on the value of C. In a meter having a throat diameter of 1 in. the effect is, however, small, except at very low velocities, so long as the width does not exceed 0.4 in. The author found that at medium and high velocities maximum values of C were

obtained with the minimum (0.015 in.) gap, and minimum values with a gap of 0.06 in. At velocities less than 0.1 ft. per second the effect of a variation in this width becomes very pronounced.

"Abnormally high values of  $\mathcal C$  at moderately low velocities are to be attributed to errors in the throat gage reading, due to the accumulation of air at the throat. Such high values are only to be anticipated in a meter in which the throat pressure is less than atmospheric, and probably only where independent measuring columns are used at entrance and at throat, and where communication between throat and measuring column takes place through a circumferential gap surrounding the throat. Where a U-tube gage or any of its modifications has been used there would appear to be no record of any such high values of  $\mathcal C$ , and such a device should be used where there is reason to anticipate negative pressures.

"An examination of all available data shows that, whatever the conditions under which a meter may be operating, the value of C varies within narrow limits so long as the pipe line velocity exceeds 1 ft. per second. This coefficient may vary from about 0.96 to slightly over unity. In the normal meter of moderate or large size a value of 0.99 will probably give the value within 2 per cent for any velocity exceeding 1 ft. per second. Where essential that the records for lower velocities should be accurate, this can only be insured by a calibration of the meter,"

Pumps for the irrigation of small areas, B. Dibble (Jour. Electricity, 37 (1916), No. 4, pp. 65-67, figs. 3).—Factors to be observed in the selection of centrifugal pumps for the irrigation of small areas are discussed.

Experiments upon the purification of sewage and water at the Lawrence Experiment Station, H. W. Clark and G. O. Adams (Ann. Rpt. Bd. Health Mass., 46 (1914), pp. 297-346).—These experiments include special studies "of the relative efficiency of trickling filters of different depths, of the disposal and utilization of sewage sludge, of the purification of sewage by aeration in tanks containing layers of slate upon which 'growths' form, etc., and of the purification or disinfection of water by means of liquid chlorin."

Sewage disposal for isolated residences, C. G. GILLESPIE (Cal. Bd. Health Spec. Bul. 8 (1916), pp. 2-8, figs. 4).—This bulletin describes the septic tank and tile absorption method of residential sewage disposal.

"The tank must be located judiciously, so that prevailing winds will carry odors in a direction away from dwellings and so that wells and watercourses will not be polluted by the effluent. Under ordinary conditions, for safety. 200 ft. should separate the tank and the nearest well, watercourse, homes, or highway."

Sanitation in the mountains, C. G. GILLESPIE (Cal. Bd. Health Spec. Bul. 10 (1916), pp. 3-20, figs. 8).—This bulletin deals with the sanitary privy and septic and Imhoff tanks for the disposal of sewage in mountain resorts.

Engineering operations for the prevention of malaria, F. D. Evans (Minutes Proc. Inst. Civ. Engin. [England], 200 (1915), pt. 1, pp. 2-61, figs. 12).—This is a presentation of the details of these operations.

Terracing in Texas, J. C. Olsen (Agr. and Mech. Col. Tex. Ext. Serv. Bul. B-23 (1916), pp. 3-32, figs. 27).—This bulletin describes and illustrates methods of erosion prevention practiced in Texas.

The use of dynamite in clearing land, E. Secrest (Mo. Bul. Ohio Sta., 1 (1916), No. 8, pp. 236-239, figs. 2).—The cost of dynamiting white oak, beech, hickory, chestnut, black oak, maple, cherry, and black gum tree stumps ranging in age from six months to 25 years and in diameter from 6 in. to 42 in. are

reported. The number of 0.5-lb. sticks of dynamite used per stump varied from 1 to 9.5, averaging 3, and the cost per stump varied from 20 cts. to \$1.68, averaging 59 cts.

Brief instructions on handling the explosive are also included.

British standard nomenclature of tars, pitches, bitumens, and asphalts, when used for road purposes, and British standard specifications for tar and pitch for road purposes, L. S. ROBERTSON (Engin. Standards Committee Rpt. 76 (1916), pp. 16).—These specifications and definitions were approved by the British Engineering Standards Committee, supported by five British national engineering societies.

Motor truck lessens cost of maintaining gravel roads in Alabama, T. H. Edwards (Engin. Rec., 74 (1916), No. 3, pp. 73, 74, figs. 6).—Working data for 650 miles of road are reported which indicate that from 16 to 20 mules may be replaced by a motor truck for pulling a scarifier, and complete scraping after every rain is made possible, the truck drawing three road machines covering 30 miles a day. The cost of hauling gravel was reduced from 30 to 40 cts. to from 7 to 11 cts. per yard-mile and included spreading on the road in addition.

Public road mileage and revenues in the Middle Atlantic States, 1914 (U. S. Dept. Agr. Bul. 386 (1916), pp. 27, fig. 1).—This bulletin contains "a compilation showing mileage of improved and unimproved roads; sources and amounts of road revenues; bonds issued and outstanding; and a description of the systems of road administration and fiscal management, and of other factors affecting road improvement in each State."

New tests of bolted joints in timber framing, H. D. Dewell (Engin. News. 76 (1916), No. 3, pp. 111-115, figs. 7).—Tests of 24 bolted joints, 10 all-timber lagscrewed joints, 4 joints in which a steel plate was lagged to timbers with \(\frac{2}{3}\)-in. lagscrews, and 13 tests made to determine the bearing resistance of a round bolt against the ends and across the fibers of Douglas fir are reported. "The author believes that the following conclusions and recommendations for working data, made from a study of the tests, are justifiable and reasonably conservative:

"For bolts with driving fit in the timbers the strength of the joint is practically independent of the thickness of the side pieces, when this thickness exceeds the limiting value 't.' While the ultimate strength of the joints whose bolts have cross-bearing in the main timber is far below that of the all-end-bearing joints, the stiffness of such joints up to the break in the curve is practically the same.

"The same loads for bolts in joints like those described, having all end bearing, may be taken as per [the following]:

"Working strength of one bolt in timber joint (bolt in double shear) for joints similar to test joints, with bolts bearing against the end of the grain.

Size of bolt.	Thickness of side pieces and one-half thickness of center timber.			
	2 in.	3 in.	4 in.	6 in.
In.	Lbs. 1,057 1,459 1,900 2,460	Lbs. 1,275 1,665 2,130 2,664	Lbs. 1,460 1,980 2,450 2,960	Lbs. 1,460 2,100 2,850 3,705
1				

[&]quot;These values correspond fairly well to one-half the loads for  $\frac{1}{16}$ -in, slip. These working loads are consistent with the results of tests on nailed joints.

"For the allowable pin pressure it is proposed that for Douglas fir and similar timbers 800 lbs. per square inch be used for cross-bearing and 1,300 lbs. per square inch for end bearing.

"For connections in which the bolts are in single shear only, as in the case of two timbers bolted together, it is recommended that the value of the bolts be taken at one-half the values given in [the] table. For connections in which the bolts bear across the fibers of the timber, it is recommended that the values of the bolts be taken at six-tenths the values given for all end bearing.

"The working values recommended are for Douglas fir. For other timbers these values are to be multiplied by the factors following: Long-leaf yellow pine, 1.05; white pine, 0.78; Norway pine, 0.65; white oak, 0.78. All working values herein given are for timber in a dry condition, as for use in the interior of buildings."

Lagscrewed joints in timber, H. D. Dewell (Engin. News, 76 (1916), No. 4, pp. 162-164, figs. 5).—Tests of 14 timber joints fastened by lagscrews, of which 4 were on joints in which a 0.5 in. steel plate was fastened to a timber block and 10 were on joints in which wooden plates 1.25 to 2 in. in thickness were lagged to an 8 by 8 in. block are reported.

"The test results show that (1) for loads up to 2,000 lbs. per screw the strength of a  $\frac{7}{8}$  in, lag is not appreciably larger than that of a  $\frac{3}{8}$  in, lag; and (2) the working values as given by Kidder correspond to a slip of 0.08 in, for the  $\frac{3}{8}$  in, screw and 0.12 in, for the  $\frac{7}{8}$  in, lagscrew. . . .

"On comparing the curves of the lagscrewed all-timber joints with those of the bolted joints it is evident that while the ultimate strength of the former is far below that of the latter for the same diameter of lag or bolt, the lagscrewed joints are stiffer for the same load, up to the break in the curve. . . As in the case of the bolted joints, there seems to be practically no reduction in stiffness for the  $\frac{7}{8}$  in, joints, in which the lagscrews bore across the fibers of the timber in the main block. This statement holds true only for loads of approximately 2,000 lbs. per lagscrew. In ultimate strength such joints are far below those having all end bearing; the failure is sudden and due to splitting of the main timbers. . . .

"With the criterion of a working strength of one-half the load corresponding to a slip of  $\frac{1}{16}$  in., the safe resistance of a  $\frac{3}{4}$  by  $4\frac{1}{2}$  in. lagscrew may be taken as 900 lbs., while that of a  $\frac{7}{8}$  by 5 in. lagscrew may be taken at 1,050 lbs. Similarly for a working slip of  $\frac{1}{3}$ 2 in. the respective resistances are 1,375 lbs. and 1,500 lbs. For joints in which a metal plate is fastened to timbers by means of lagscrews it is believed that the values of 900 lbs. for a  $\frac{7}{8}$  by 5 in. lagscrew and 770 lbs. for a  $\frac{3}{8}$  by  $4\frac{1}{2}$  in. lagscrew are reasonable working values and that 1,300 lbs. and 975 lbs., respectively, should be the maximum allowable capacity used. For all-timber lagscrewed joints similar to those tested the value of 1,050 lbs. for a  $\frac{7}{8}$  in. lag and 900 lbs. for a  $\frac{3}{8}$  in. lag are recommended for design, with a maximum of 1,500 lbs. and 1,375 lbs., respectively. All working values advocated are for timber in a dry condition and for use in interior building construction."

Rules for conducting performance tests of power plant apparatus (Amer. Soc. Mech. Engin., Rpt. Power Test Com., Codes of 1915, pp. 215, figs. 27).—This includes, among other things, sections on the testing of pumping machinery, gas and oil engines, and water wheels.

Directory and specifications of gasoline and oil farm tractors (Farm Machinery, No. 1293 (1916), pp. 52, 53, 55, 56).—This list includes 189 tractors of 114 different makes.

A standard drawbar rating for tractors, R. Olney (Farm Machinery, No. 1291 (1916), pp. 13-15, figs. 2; Power Farming, 25 (1916), No. 8, pp. 9, 50-52, fig. 1).—In an address before the National Gas Engine Association, the author advocates the rating of tractors on the basis of the actual pounds of pull developed at the drawbar instead of on the horsepower basis and reports experimental data to substantiate his argument. Motor torque and brake horsepower curves, reproduced from the data obtained from an actual prony brake test on a  $3\frac{1}{2}$  by  $5\frac{1}{4}$  tractor motor of the 4-cylinder, heavy-duty type, are given showing that the torque and likewise the pounds of drawbar pull remain practically constant throughout a wide range of motor speeds, while the brake horsepower varies directly as the speed up to a certain point.

"A prony brake test should be made on the motor to obtain data for determining the torque and brake horsepower at various speeds. The torque curve of any motor . . . will indicate the normal or critical speed of the motor or the speed at which the motor produces the greatest torque. The brake horsepower rating should be given on the basis of the torque produced at this speed. The basis for the drawbar rating should be the pounds pull exerted in an actual pulling test. The drawbar test should be made with the motor running at its critical speed and with the tractor traveling at its best working speed as fixed by the gear ratio."

Controlled tests of mechanical cultivating apparatus, RINGELMANN ET AL. (Compt. Rend. Acad. Agr. France, 2 (1916), No. 22, pp. 609-615).—This is a review and summary of the results of several different trials.

Tobacco-curing barns, E. G. Moss (N. C. Agr. Ext. Serv. Circ. 18 (1916), pp. 9, figs. 5).—This circular, prepared under a cooperative agreement between the North Carolina Experiment Station and the U. S. Department of Agriculture, reports an experiment in tobacco curing begun in 1911, the object being to determine where more uniform curing, considering weather conditions and varying amounts of water in the tobacco at the time of curing, can be made and "whether the fuel consumption could not be materially reduced by using tight barns fitted with proper ventilators so placed in the barn as to keep a current of air circulating through the tobacco when needed.

"For this experiment two 18-ft. log barns were used. On one of these the old roof was replaced by a tight cover of galvanized V-crimp iron. Between the sheeting 1-in. strips were nailed to prevent air escaping around the eaves of the roof. The barn was daubed inside and out so as to make it as nearly air-tight as was practical. Seven 4-in. pieces of terra cotta pipe 2 ft. long were placed in the underpinning of the barn, the bell of the pipe being flush with the outside of the barn and extending inside the barn and delivering the air either under or against the sheet-iron pipes used as flues. By this means the air is slightly heated before coming in contact with the tobacco, and consequently more quickly absorbs the moisture from the green tobacco. A type of inverted trough ventilator . . . was placed on top of the barn . . . The second barn . . . was covered with boards, was well daubed outside, and fitted with the same size furnaces and flues as the tight barn. Each of these barns would hold about 400 sticks of cut tobacco."

It was found that a saving of  $2\frac{1}{8}$  cords of wood was effected in the tight barn during four curings, which is considered to be a considerable advantage. Plans and a bill of material for a barn of this type are included.

Lightning rods; their functions and good qualities, T. Croff (Farm Machinery, No. 1293 (1916), pp. 35-37, figs. 8).—This article deals with the development and effectiveness of lightning rods and with their installation and protection.

#### RURAL ECONOMICS.

The elements of an ideal rural civilization, II. J. WATERS (Proc. Soc. Prom. Agr. Sei., 36 (1915), pp. 7-15).—In this address, delivered before the meeting of the Society for the Promotion of Agricultural Science at Berkeley, Cal., in August, 1915, the author summarizes what he considers the elements of an ideal rural civilization as follows:

"Opportunities for the rural people equal to those of the town people and the power and inclination of the rural people to live up to their opportunities, or to phrase it more tersely, income and idealism, are the two elements out of which a stable and satisfactory rural civilization will be built. A society having for its object the promotion of the science of agriculture can not afford to exalt one of these elements above the other."

Some effects of war conditions on agriculture, A. Smetham (Jour. Roy. Lancashire Agr. Soc., 1916, pp. 25-48).—Among the effects to which attention is called in this article is the scarcity of commercial fertilizers and commercial feeding stuffs.

Women and the land, VISCOUNTESS WOLSELEY (London: Chalto & Windus, 1916, pp. XI+230, pls. 12).—This book discusses the relationship of women to the problems of English agriculture, not only from the viewpoint of present war conditions, but also in relation to future development. Among the topics treated are the peasant class of the future, cooperation, women's institutes, better housing conditions, better farm wages, village industries, the education of farm women and girls, and the women gardeners of the future.

Cur country church problems, E. C. Branson (Univ. N. C., Ext. Bur. Circ. 1 (1916), pp. 10).—The author discusses the influence of rural migration, farm tenancy, and absentee preachers upon the rural church problem, and advocates the establishment of a country church with home-resident ministers receiving living salaries.

Factors affecting interest rates and other charges on short-time farm loans. C. W. Thompson (U. S. Dept. Agr. Bul. 409 (1916), pp. 12, pls. 2).—Among the factors discussed are the natural conditions affecting agriculture, distance from financial centers, character of the borrowers, methods and character of farming, and characteristics of the loan and the relation of the farmer to the loan agency.

Influence of age on the value of dairy cows and farm work horses, J. C. McDowell (U. S. Dept. Agr. Bul. 413 (1916), pp. 12, figs. 5).—These estimates are based on information obtained from men who have had wide experience with the class of live stock on which they have furnished information. In order to eliminate everything except age, the animals were assumed to be in perfect health and to have a fixed value at a certain age. The estimates for each breed of dairy cattle were based on four classes of 3-year-olds, namely, the \$\$0-grade cow, the \$100-grade cow, the \$200 pure-bred cow, and the \$300 pure-bred cow. The farm work horse was assumed to have a maximum value of \$250 when in his prime.

It was found that for all breeds and for all classes of breeds, the prices of cows in health is greatest between five and seven years with the maximum usually at six years. Cows are valued about the same at four as at eight years. The author's explanation is that although the younger animals have before them a long period of usefulness the older ones have already demonstrated their work. In all the estimates the 14-year-old values for pure-bred cows were much greater than for grades.

The farm work horse seems to reach his maximum value at some point between six and seven years of age. As compared with the values given for purebred dairy cattle of about the same maximum value, the birth value of the horses is considerably less, the age of maturity a little later, and the old-age value somewhat higher.

The normal day's work of farm implements, workmen, and crews in western New York, H. H. Mowry (U. S. Dept. Agr. Bul. 412 (1916), pp. 16).—The information made available in this bulletin was obtained by a circular of inquiry from farmers in Wayne, Ontario, Monroe, Genesee, Livingston, Orleans, and Niagara counties, and relates to such farm operations as plowing, harrowing, and rolling and operations in connection with the planting and harvesting of grain crops, the handling of manure, haying, and the care and harvesting of cabbage and fruit crops.

Systems of renting truck farms in southwestern New Jersey, H. A. Turner (U. S. Dept. Agr. Bul. 411 (1916), pp. 20).—The farms from which records were secured were in Gloucester, Salem, and Cumberland counties. The farms were subdivided into early and late truck farms and also classified according to the methods of renting. Among the more general conclusions brought out by this study was that the average labor income of 186 farms let for a half share of the crops was \$223 for the tenant and 6.8 per cent on the landlord's investment. The average for 35 farms let for cash was \$206 for the tenant and 3.7 per cent on the landlord's investment. The bulletin discusses in detail the incomes and system of farming as carried on by the farmers under the various classifications noted above.

The logged-off lands of western Washington, H. F. GILES (Olympia, Wash.: Bur. Statis. and Immigr., 1915, rev. ed., pp. 64, pl. 1, figs. 16).—This report contains information regarding the available logged-off lands and methods of clearing and of farming such lands.

The country elevator in the Canadian West, W. C. CLARK (Queen's Quart., 24 (1916), No. 1, pp. 46-68).—The author describes the development of the elevator systems, difficulties encountered, and the present status.

Transportation of agricultural products in Argentina (Valor de la Producción Nacional su Transporte Ferroviario—Capacidad de Depósitos Graneros en Estaciones y Puertos. Buenos Aires: Min. Agr. Nac., 1916, 2. ed., pp. 69).—in this volume is given information regarding the transportation of the different cereals, forest products, and live stock and live stock products over the various railway systems of Argentina.

Marketing perishable farm products, A. B. Adams (Columbia Univ. Studies Polit. Sci., 72 (1916), No. 3, pp. 180).—The author has attempted to point out the fundamental forces which underlie the marketing of fruit, vegetables, and dairy and poultry products, and to suggest methods of controlling these forces so that the cost of marketing may be reduced.

He claims that the social burdens incident to the marketing of perishables are due to two main causes—to the inherent characteristics of the goods themselves and to the imperfections in the methods and processes by which they are marketed. Because of the natural perishability of the goods many of them become unfit for consumption before they can be offered to consumers. The natural seasonal production of the goods creates temporary surpluses in the available physical supply which adds greatly to the decay of the goods by lengthening the average time between their harvest and consumption. The burden of marketing them is further increased because they are goods which must be produced by a small business unit (the farm) and consumed by a smaller one (the family).

He further states that "if we are to reduce the social costs of marketing perishables through a reform in the system of marketing, it must be done by finding cheaper and more efficient ways of performing the complicated processes, not by reducing the number of those processes."

Cooperation for fruit growers, A. F. Mason (Proc. State Hort. Assoc. Penn., 57 (1916), pp. 52-60, pls. 4).—Among the methods suggested for improving the methods for the marketing of fruit are standardization of the product through methods of packing and growing, cooperative purchase of supplies, cooperative advertising, centralization of selling and distribution, utilization of by-products, and the employment of efficent managers.

Rural cooperation, E. LAHITTE (La Cooperacion Rural. Buenos Aires: Min. Agr., 1915, 2. ed., pp. 92).—This book contains a brief description of cooperative organizations as found in Italy, France, Austria, Germany, Argentina, and the United States.

Report of the proceedings of the ninth congress of the International Cooperative Alliance, 1913 (Rpt. Proc. Cong. Internat. Coop. Alliance, 9 (1913), pp. XLVIII+163, pls. 11).—Among the topics discussed at this congress, held at Glasgow. August 25–28, 1913, were The Direct Exchange of Goods between Distributive Societies, Agricultural, and other Productive Societies, also between the Wholesale Societies in the Different Countries, by H. Kaufmann; The Closer Relationship and Mutual Help of Cooperative Societies and the Comprehensive Character of the International Cooperative Alliance, by A. Williams; The Development of the Cooperative Press in the Interests of Cooperative Education, by O. Schär; and The Plurality of Distributive Societies Having their Seat in the Same Locality, by L. Buffoli and C. Mellini.

Business practice and accounts for cooperative stores, J. A. Bexell and W. H. Kerr (U. S. Dept. Agr. Bul. 381 (1916), pp. 56, pl. 1).—The authors have outlined a simple and adequate system of records for cooperative retail stores and pointed out fundamental business methods that must be observed to insure success. They have discussed this subject under the headings of corporate records, statements and reports, operating records, auditing, and office equipment. The bulletin outlines in detail the necessary records and statements essential to the proper conducting of the store under a cooperative scheme and gives a large number of model forms.

A system of accounts for live-stock shipping associations, J. R. Humphrey and W. H. Kerr (U. S. Dept. Agr. Bul. 408 (1916), pp. 14).—There have been described in this bulletin types of shipping agencies and methods of financing shipping associations, together with methods for keeping the accounts of such associations. The authors have outlined a system in which the only books of record required are a cash journal, consisting of a multi-column cash book and journal combined, with a provision for a detailed account of sales of supplies, and an ordinary form of loose-leaf ledger. They have also described other forms that may be used, such as the shipping record envelopes, members' receipts, members' account sales, manifests, sales tickets, and cash receipts. Sample forms are also included in the bulletin.

Price Current Grain Reporter Yearbook, 1916, E. G. Osman (*Price Current Grain Rptr. Yearbook 1916*, pp. 88).—This continues data previously noted (E. S. R., 34, p. 393), giving statistics for later years.

Returns of produce of crops in England and Wales (Bd. Agr. and Fisheries [London], Agr. Statis., 50 (1915), No. 2, pp. 81-101).—This continues data previously noted (E. S. R., 33, p. 894), adding statistics for later years.

Agricultural statistics of Argentina, 1914-15 (Estad. Agr. [Argentina], 1914-15, pp. 186).—This report continues information previously noted (E. S. R., 35, p. 91), adding data for later years.

[Agricultural statistics of Sweden] (Statis. Årsbok Sverige, 1916, pp. 60-76).—This continues data previously noted (E. S. R., 33, p. 395), adding statistics for later years.

Agricultural statistics of Roumania (Min. Agr., Statis. Agr. României, 1915. pp. 35).—This report contains statistical data showing for 1915 the acreage, average yield, and total production of the principal agricultural crops by Provinces, with comparative data for 1909–1914 for Roumania as a whole.

[Agriculture in Egypt] (Ann. Statis. Egypte, 6 (1914), pp. 319-371; 7 (1915), pp. 107-181).—This continues data previously noted (E. S. R., 32, p. 894), giving statistics for later years.

#### AGRICULTURAL EDUCATION.

The Cook County system of rural education, E. J. Tobis (Ill. Agr., 20 (1916), No. 8, pp. 705, 706).—The Cook County (Ill.) course in school-home projects is briefly described. The course comprises field and garden, poultry, cow testing, music, sewing and cooking, and business projects.

To provide a close supervision of the work the county is divided into five divisions, each in charge of a country life director whose duty it is to supervise and direct all school-home projects, recreation, and school work in his division. He must see that all pupils over 10 years of age take at least one school-home project as a part of their regular school work. Each director had charge of about 25 schools with a total attendance of 500 pupils in 1915. Additional supervision was found necessary for the summer vacation, and the county provided \$2,800, which allowed each country life director \$500 for additional supervision of school-home projects in his division. Fifteen "wandering" supervisors were selected for their efficiency in this work by the directors from among their own teachers, so that each pupil's project was visited about once a week.

The author, who is county superintendent, finds this supervision of great value in that it takes the teacher directly into the homes, makes the school a force in the community by linking the pupil's work with the family life and the rural business of the farm, and directs the pupils' energy in a proper way during the summer vacation months. By this method the school period is extended, the rural school is placed on a basis of efficiency, and the parents become interested and willing to cooperate.

The net profits from the school-home project belong to the pupil and must be banked, loaned, or wisely expended. Each pupil is obliged to keep an itemized account of his receipts and expenditures. All pupils who successfully carry through a school-home project are publicly gravted an achievement emblem, consisting of a four-pointed star, and year after year silver stars are welded in the emblem as a recognition for completion of further projects. A magazine, Achievement, devoted to the interests of pupils carrying on school-home projects, is published annually.

[Agricultural education in New Brunswick in 1915], R. P. Steeves, R. Newton, and Hazel E. Winter (Rpt. Agr. New Brunswick, 1915, pp. 6-24, 91-96, pls. 6).—Included in this report of the department of agriculture of New Brunswick for 1915 are the reports of the director of elementary agricultural education, the director of agricultural schools, and the supervisor of women's institutes.

Instruction in nature study and agriculture was given to 2,711 pupils (an increase of 1,355 over the previous year) through 48 school gardens, an increase of 16 gardens over the previous year. The number of home plats conducted by pupils under the supervision of teachers increased from 59 to 378.

The success of the first rural science school in the Province for the training of teachers in nature study and elementary agriculture in 1914, at Woodstock, led to the organization of two such schools—at Woodstock and Sussex—during the past summer. The enrollment at these schools was 65 and 115, respectively. The first school fair was held during the year. The work of the agricultural schools at Woodstock and Sussex was limited to short courses of from a few days to 6 weeks in length, but it is planned to develop longer courses as the work progresses. There are now 80 women's institutes with a total membership of 2,400. Their activities included patriotic work, agricultural lectures, exhibits, and short courses.

The General Direction of Agricultural Instruction (Min. Agr. Argentina, Mem. Cong. Nac., 1913, pp. 67-89).—Brief reports are given on the work in 1913 of the agricultural education service in Argentina, including 4 technical or special agricultural schools, 11 district practical agricultural schools of which 3 are in process of organization, agricultural extension work by 20 district agronomes, and 7 experiment stations in connection with agricultural schools.

[Agriculture and forestry instruction in Austria] (Land u. Forstw. Unterrichts. Ztg., 29 (1915), No. 3-4, pp. IV+99-226, figs. 7).—This number contains (1) special articles as follows: The Reform of the Final Examination at the Intermediate Agricultural Schools, by K. Kolb; Forty-Year Development of the Intermediate Agricultural School at Prerau, Moravia, by J. Adamec; The Four-Year Course at the Francisco-Josephinum, by E. Vital; The Present Status of Instruction in Fishery at the Agricultural and Forestry Schools in Austria, Together with Suggestions for Its Future Organization, by O. Haempel; and The Agricultural Schools and the Care of (War) Invalids, by A. Kastner; (2) a review of progress in 1914-15 of the agricultural and forestry institutions of Austria; (3) a review of agricultural literature; and (4) notes.

Tentative course of study for United States Indian Schools (*U. S. Dept. Int.*, Off. Indian Aff. [Pub.], 1915, pp. VI+3-293).—This course, prepared under the direction of the Commissioner of Indian Affairs, has been planned with the vocational aim very clearly and positively dominant, with special emphasis on agriculture and home making. It consists of three divisions, namely, primary (first 3 grades), prevocational (grades 4-6, inclusive), and a vocational 4-year course above the sixth grade. Outlines of the course for each year are followed by a description of the subjects.

Gardening is given in the first 2 grades and the study of plants in the third. The prevocational work includes instruction in gardening, dairying, stock raising, plant production, roads, care of implements, and beautifying home grounds, farm carpentry and blacksmithing, farm engineering, farm masonry, painting and shoeing, and harness repairing. There are given to class instruction 1½ hours per week and 22½ hours to practical application. In the vocational course class instruction is given in agricultural botany, soils and soil fertility, farm and household physics, agricultural chemistry, field crops, plant diseases, insects and insecticides, and rural economics, 20 weeks each; and farm practice in farm implements, horticulture, types and breeds of farm animals, and feeds and feeding, each 40 weeks, with 1½ hours a week of instruction and 22½ hours a week of application.

For the girls instruction is given in the first 3 grades in sewing, lace making, housekeeping, cooking, planning and serving meals, care of cows and milk, butter making, kitchen gardening, and poultry raising. In grades 3 to 6 theoretical and practical instruction is given in home training, including the care of the house, water supply, personal hygiene, housekeepers' responsibilities, motherhood, child welfare, cooking, poultry raising, sewing, laundering.

and nursing. The 4-year vocational course endeavors to train Indian girls to become model housewives, and includes 4 years of theoretical and practical instruction in cooking, sewing, and nursing.

Methods of instruction in agriculture, E. S. Sell (Bul. State Normal School [Athens, Ga.], 3 (1916), No. 3, pp. 29).—This bulletin contains 42 lessons for recitation and 34 exercises, each requiring a class period, adapted to the rural and village schools of Georgia, and arranged on a seasonal sequence plan. The work can be given in 2 lessons a week for 9 months or 3 lessons a week for 6 months, and includes a study of general principles underlying plant production, field crops, fertilizers and soils, animal hunbandry, poultry raising, farm implements, and farm communities.

Suggestive outlines for agriculture work in rural and village schools: Potatoes, L. G. Atherton (Normal Teacher [Madison, S. Dak.], 4 (1915), No. 4, pp. 16, figs. 5).—Outlines are suggested for the use of teachers in rural and village schools in giving theoretical and practical instruction in potato growing.

Practical lessons in tropical agriculture, Books II, III, R. L. CLUTE (Yonkers, N. Y., and Manila, P. I.: World Book Co., 1916, pp. X+258, pl. 1, figs. 166; VII+251, pl. 1, figs. 120).—Book II discusses the importance of agriculture, the farm as a place of business and as a home, farm implements and their use, and preventing losses on the farm; continues the study of the principles of agriculture begun in Book I (E. S. R., 33, p. 397); and considers the application of these principles in the growing of field crops important in the Philippines, including rice, coconuts, abaca, sugar, corn, tobacco, other fiber plants, and other farm crops. Studies of the silk industry and of poultry raising are included. Each chapter includes practical exercises.

In Book III, the author discusses some of the more important fodder crops and pasturage, legumes, some minor farm crops, crop rotation, fruits on the farm, forests, the farmer's friends and enemies, weeds, farm animals including the horse, cattle, carabaos, swine, goats, and sheep, and their diseases, farm management, business methods for the farmer, business and legal papers, agricultural fairs and food campaigns, aids for the farmer, and field excursions and home projects. Lists of shade trees and decorative plants and agricultural literature, instructions to homesteaders in the Philippine Islands, and directions for organizing a better farming club are appended. Suggestions to the teacher are included.

Nature study preceding agriculture, A. W. Nolan (School News and Pract. Ed., 29 (1916), No. 10, pp. 453-455).—Suggestions are offered for nature study work in grades 1 to 6, inclusive.

In the author's opinion, nature study should be pre-vocational to agriculture before the seventh grade of the public school. It should be differentiated from technical science both in subject matter and method, and should aim to give a general acquaintance with and an interest in the common things and processes of nature, a training in accurate observation as a means of gaining knowledge direct from nature, and useful knowledge concerning natural objects and processes as they directly affect human life interests. The materials to be studied must be those most common and most interesting from the standpoint of everyday life, and finally nature study must be for the child and not for the adult.

The plant notebook, Anna B. Comstock (Ithaca, N. Y.: Comstock Publishing Co., 1915, pp. 126, figs. 37).—This notebook contains a study of the different parts of a plant, followed by questions and blanks for the description of plants studied by the pupils.

Lessons on tomatoes for rural schools, E. A. MILLER (U. S. Dept. Agr. Bul. 392 (1916), pp. 18, figs. 5).—The author outlines 10 lessons in a study of the history, importance, and varieties of tomatoes, and the many phases involved

in growing, harvesting, and marketing the crop. Each lesson includes classroom work, practical exercises, references to literature, and suggestions for correlations with other school work. Directions are given for organizing tomato clubs and preparing community exhibits.

The structure of the common woods of New York and the wood collection, distributed by the College of Forestry, R. P. PRICHARD (Syracuse Univ. [Pubs.], 15 (1915), No. 3, pp. 31, figs. 4).—This bulletin, which has been prepared for high school pupils especially, contains a description of the structure of the common woods of the State of New York, followed by a key to the species, together with information concerning the characteristic purpose and uses of the woods contained in a collection of 31 different woods in the form of hand specimens which in size are the same as the ordinary card index card. This collection has been prepared and is distributed by the New York State College of Forestry at Syracuse University for use by teachers and pupils interested in biology, nature study, and forestry.

The boy scout's forest book, R. Black (Ottawa, Canada: The Canadian Forestry Association [1916], pp. 31, figs. 25).—This book is one of a series which the Canadian Forestry Association will present to the boy scouts of Canada to acquaint them with the economic importance of forest conservation and methods of preventing and fighting forest fires.

The teaching of entomology in public schools, L. A. Dewolfe (Proc. Ent. Soc. Nova Scotia, No. 1 (1915), pp. 98, 99).—The author gives reasons for the teaching of entomology as a nature study topic in the public schools, and suggestions for teaching the subject.

Development in animal husbandry instruction, C. S. Plumb (Agr. Student, 22 (1916), No. 9, pp. 612-615, figs. 7).—The author gives a brief account of how live stock ideas were introduced into the agricultural colleges of Massachusetts, Michigan, Ontario, and Wisconsin. He believes that the first attempt in America to teach animal husbandry subjects in a systematic manner, accompanied by laboratory practice, was made by the Ontario Agricultural College, and that the first distinctive animal husbandry courses in the United States were given in 1890 at the University of Wisconsin by the late Prof. John A. Craig.

Home economics instruction (Cong. Internat. Enseig. Ménager, 2 (1913). Compt. Rend., pp. 258; Raps. Sects. 1, pp. 115; 2, pp. 111, figs. 2; 3, pp. 78; 4, pp. 319).—This is a report of the proceedings of the general session and of the meetings of the four sections of the Second International Congress of Home Economics Instruction, held at Ghent, June 15–19, 1913. It includes the papers presented at the section meetings dealing with the following subjects: (1) Home Economics Instruction in the Family and the Elementary School, (2) Home Economics Instruction for Adults or In Connection With Secondary Instruction. (3) The Training of Teachers of Home Economics, and (4) The Progress of Home Economics Instruction in the Different Countries and the Importance of this Instruction from the Individudal, Family, National, and Social Standpoints.

High school food work, what besides manipulation? Emma Conley (Proc. Cent. Assoc. Sci. and Math. Teachers, 14 (1914), pp. 167-171).—In this discussion the author holds that the art of simple cookery could and should be attained in the grades, or if not given in the grades, in the first few months of the freshman high-school year; in addition to this, food work should be taken up from the standpoint of its relation to the actual conditions which prevail in 85 per cent of the homes of the country, and the cost, digestibility, and nutritive value of the food prepared should form an important part of the lesson to supplement the practical work and thus give it educational value for high school pupils.

Household management in the high school, Bernick Allen (Proc. Cent. Assoc. Sci. and Math. Teachers, 14 (1914), pp. 151-154).—The author gives her experience in teaching household management for the first time to high school girls. The work was centered around the preparation of food and cleaning, keeping in mind their scientific, economic, and civic aspects, and considering the relative values of each of the different household activities. The class met for single periods of 45 minutes every day for one semester.

Teaching of food through preparation of meals, Agnes Wilson (*Proc. Cent. Assoc. Sci. and Math. Teachers, 14* (1914)] pp. 154, 155).—This paper briefly describes the work of two practical housekeeping centers in the tenement district of Chicago.

High school dietetics, Ada Hillier (Proc. Cent. Assoc. Sci. and Math. Teachers, 14 (1914), pp. 158-160).—Suggestions are offered on when and how to teach dietetics in the high school.

First lessons in cooking, Cora B. Miller (Fort Dodge, Iowa: Supervisor Dom. Sci. and Dom. Art Fort Dodge Pub. Schools [1916], pp. 58, figs. 2).—This text for elementary schools is arranged in 36 lessons, and comprises a study of the different foods classified on the basis of composition and origin, their economic and food values, and directions for cooking and planning and serving meals. Supplementary lessons, instructions on hygiene, and suggestions for rural school work are appended.

Drafting in dressmaking classes, Agnes K. Hanna (Proc. Cent. Assoc. Sci. and Math. Teachers, 14 (1914), pp. 161-166).—The author discusses the value of pattern drafting in general school work and in vocational training in the needle trades, the selection of the drafting system to be used in class work, and the method of presentation. It is found that drafting as an end in itself is "of value only to the highly specialized pattern maker. Its value lies in its ability to offer a comprehensive and effective study of certain principles of line which are fundamental in garment construction, its essential value being the economy of effort which this study should secure in comparison with the more empirical method of experimentation."

Teaching house decoration in the high school, ISABEL CLARK (*Proc. Cent. Assoc. Sci. and Math. Teachers, 14 (1914), pp. 156-158*).—A brief account is given of how a course in house decoration was presented in one period a week to the sophomore girls in the domestic art class at the high school in Oshkosh. Wis.

Woodworking problems, S. T. Newton (Manitoba Agr. Col. Bul. 20 (1916), pp. 69, figs. 32).—These problems for members of boys' and girls' club contests have been prepared to teach them how to handle the ordinary carpenter's tools and how to read working drawings. Projects have been chosen that are useful around the farm home, including a poultry fattening crate, milking stool, farm gate, etc.

#### MISCELLANEOUS.

Annual Report of Florida Station, 1915 (Florida Sta. Rpt. 1915, pp. CXXXI+XI, figs. 14).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1915, a list of the publications of the year, a general review of the work of the station during the year, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue. Analyses of Japanese cane are also included.

Report of the Guam Agricultural Experiment Station, 1915 (Guam Sta. Rpt. 1915, pp. 43, pls. 7, figs. 4).—This contains reports of the agronomist in charge and the animal husbandman and veterinarian, and apicultural notes.

The experimental work recorded is for the most part abstracted elsewhere in this issue.

Work and progress of the agricultural experiment station for the year ended June 30, 1915 (Missouri Sta. Bul. 141 (1916), pp. 58, figs. 10).—This contains the organization list, a report of the director on the work and publications of the station, and the work of the college-extension service, and a financial statement for the station as to its Federal funds for the fiscal year ended June 30, 1915. The experimental work reported and not previously noted is for the most part abstracted elsewhere in this issue.

Fourteenth Annual Report of the Wisconsin Agricultural Experiment Association, 1916 (Ann. Rpt. Wis. Agr. Expt. Assoc., 14 (1916), pp. X+124, pls. 11).—This report contains addresses and discussions at the annual meeting, including a report on the association's cooperative experimental work, and other data.

Monthly Bulletin of the Ohio Experiment Station (Mo. Bul. Ohio Sta., 1 (1916), No. 8, pp. 225-256, figs. 6).—This contains several articles abstracted elsewhere in this issue; Wheat Experiments, by C. G. Williams, an abridgement of Bulletin 298 (E. S. R., 35, p. 534); and the following special articles: County Cooperation to Control Hessian Fly, by H. A. Gossard and G. R. Eastwood; Cockroaches and Their Control, by V. R. Haber; Potato Exhibits, by S. N. Green; Handling the Weed Situation, by A. D. Selby; Classification of Soils in a Soil Survey, by W. C. Boardman; and Low-Grade, Ready-mixed Fertilizers, by C. E. Thorne.

A note book of agricultural facts and figures, compiled by R. C. Wood et al. (Madras: Agr. Col. Coimbatore, 1916, 2. ed., pp. 188, pl. 1, figs. 22).—This handbook has been prepared with special reference to use in South India, and contains much information regarding weights and measures, buildings and roads, machinery, soils, manures, crops, foods and feeding, live stock, agricultural labor, insect pests, horticulture, forestry, statistical data, etc., of the region.

Masonry bases for the installation of microscopes and their accessories, including the camera lucida and the microscopic camera, N. A. Cobe (Trans. Amer. Micros. Soc., 35 (1916), No. 1, pp. 7-22, pls. 4, fig. 1).

# NOTES.

Illinois University and Station.—The resignations are noted of Clarence C. Logan, assistant in soil extension; Ward H. Sachs, associate in chemistry; Clyde R. Newell, instructor in farm mechanics; and F. C. Richey, assistant in soil physics. E. A. White has returned from a two years' leave of absence at Cornell University and resumed his duties as assistant professor in farm mechanics.

Purdue University and Station.—The new biology building is under construction and is expected to be ready for occupancy in March, 1917.

J. D. Luckett, assistant chemist in the station, has accepted an appointment on the staff of *Experiment Station Record* in the section of field crops and has entered upon his duties.

Iowa College and Station.—A new dairy barn, designed as a model as to arrangement and construction, is being erected on the college dairy farm.

A total of 3,181 requests for blueprint plans for self-feeders were received at the station from October, 1915, to June, 1916.

New projects begun by the station include studies of the specific nutritional effects of rations upon swine and sheep, the feeding of rape silage to swine, the water requirements of dairy cows when on succulent feeds, and the digestibility of Sudan grass.

Arthur S. Thurston has been appointed assistant professor of floriculture and truck crops. L. S. Gillette, assistant professor of dairy husbandry in the college, has been appointed assistant chief in dairy husbandry in the station.

Minnesota Station.—A two-story institute hall has been completed at the Duluth substation. The first floor contains an auditorium and office space, and the second, dormitory accommodations, a kitchen, and a dining room. The new equipment will make possible the holding of community gatherings at the substation, as well as afford a meeting place for various farm organizations of northeastern Minnesota.

Missouri Station.—The department of animal husbandry has been authorized to spend a balance of \$2,000, remaining from its biennial appropriation, in the purchase of pure-bred live stock.

Charles G. Carpenter has been appointed assistant in horticulture and John B. Smith assistant in farm crops.

New Hampshire College and Station.—Dr. Charles H. Otis has resigned as instructor and assistant botanist to accept a position in the biological laboratory of Western Reserve University.

New Jersey Stations.—D. Manley Jobbins, for a number of years florist and in charge of the greenhouses, died November 11.

Ohio State University.—The new home economics building is approaching completion. It is a three-story brick building, costing about \$150,000, and containing, among other features, a textile laboratory, a large room for work in instructional management, an experimental flat for courses in house decoration and household management, quarters for the extension department, and an auditorium seating about 500 people.

West Virginia University.—Dr. C. H. Winkler has been appointed professor of rural education, vice M. J. Abbey, resigned.

## INDEX OF SUBJECTS.

Note.—The abbreviations "Ala. College," "Conn. State," "Mass.," etc., after entries refer to the publications of the respective state experiment stations; "Alaska," "Guam," "Hawaii," and "P. R." to those of the experiment stations in Alaska, Guam, Hawaii, and Porto Rico; "Can." to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.
